Elevated methane concentrations (up to 54 ppm) were measured ~150-200 ft E of SS-25, probably from multiple naturally occurring holes on the side of the hill.

Methane levels immediately W and NW of well SS-25 have been decreasing during the past few days.

SCAQMD inspectors used a portable TVA-1000 monitor to confirm these findings and complement the LICOR data.

Videos were taken with FLIR cameras to identify the presence of natural gas.
