The PAR 1146.2 analysis previously considered negligible incremental maintenance and labor costs, since the requirement for zero-emission units is at the end of natural gas-fired unit age, when similar costs will be required for another natural gas-fired unit. Stakeholders commented that installation costs for heat pumps are higher than for gas units, not including equipment costs, and staff increased the unit capital cost of the zero-emission units in the cost-effectiveness analysis by 20 percent to represent additional installation and other costs. For some units this may be an overestimate, for some it may be an underestimate so applying the additional costs to all units is a conservative assumption. As heat pump installations become more commercially available and common, installation costs are anticipated to be comparable to installation costs for conventional units.

Electrical Panel Upgrade Cost

In some instances, the transition to zero-emission units will require the electrical panel to be upgraded, which will add costs for the owner or operator of the units. For the cost-effectiveness analysis, the analysis relied on the panel upgrade cost estimate of \$5,000 from the 2022 AQMP and considered a useful life of 30 years for the panel. However, the cost of an electrical panel upgrade was adjusted to account for this longer useful life of the electrical panel versus the unit. For panel upgrade cost in the PAR 1146.2 cost-effectiveness calculation, \$2,500 was utilized for pool heaters (considering the 15-year useful life) and \$4,200 was utilized for other categories (considering the 25-year useful life). For some categories involving residential units, the panel cost was split in half to account for use by multiple residential appliances. Additionally, staff assumed that 50% of residential buildings would require a panel upgrade. Data from TECH Clean California, the state-wide heat pump rebate program, showed that 9% of residential buildings required a panel upgrade. Staff expects 50% to be an overestimate but is utilizing the more conservative estimate in the analysis. Electrical panel upgrades will not be required for all instances where conventional units are replaced with zero-emission units, so staff assessed the cost-effectiveness with and without the estimated cost of the upgrades.

Applicable Units Recategorization

PAR 1146.2 defines additional categories for Type 1 and Type 2 units, shown in the figure below.

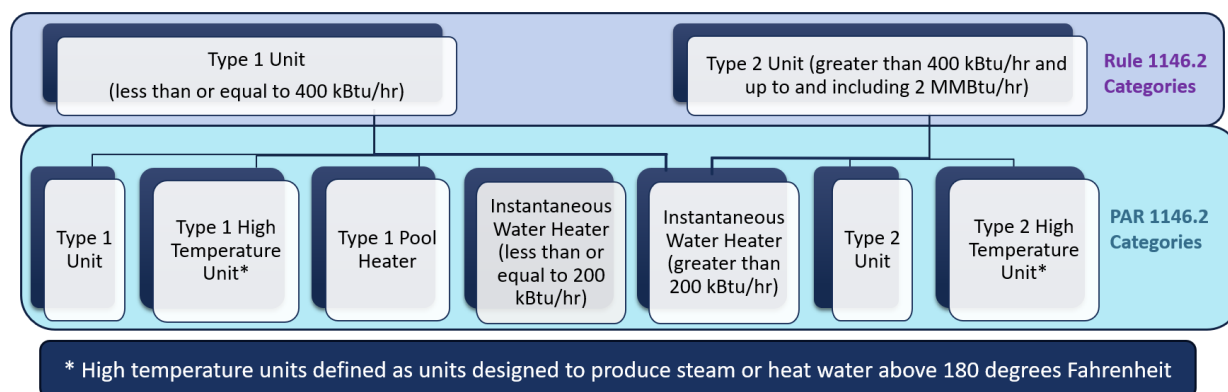

Figure 2-3-4. PAR 1146.2 Applicable Units Recategorization

Type 1 Water Heaters

For storage water heaters, U.S. DOE estimates a useful life of 10 to 15 years.¹³ For the 2022 AQMP Control Measure C-CMB-01 development, the analysis assumed a 15 year useful life for commercial water heaters.¹⁴ For this reason, the analysis for Type 1 water heaters assumes a 15-year useful life and four percent discount rate and thus a PVF of 11.118, as calculated per Equation 2-2, and the estimated cost of an electrical panel upgrade of \$2,500.

Type 2 Water Heaters

Meetings and site visits with manufacturers during the rulemaking process indicated a useful life of under and over 25 years for gas-fired water heaters. For Type 2 water heaters, the analysis assumes a 25-year useful life and four percent discount rate thus a PVF of 15.622, as calculated per Equation 2-2, and the estimated cost an electrical panel upgrade of \$4,200.

Type 1 Pool Heaters

According to U.S. DOE, heat pump swimming pool heaters work efficiently as long as the outside temperature remains above the range of 45 to 50 degrees Fahrenheit. The cooler the outside air that a heat pump draws in, the less efficient it is. However, as outdoor pools are more frequently used during warm and mild weather, this reduced efficiency is generally not an issue. Heat pump pool heaters may cost more than natural gas-fired pool heaters, but they typically have much lower annual operating costs due to their higher efficiency. With proper maintenance, heat pump pool heaters typically last longer than gas pool heaters. U.S. DOE estimates that with proper installation and maintenance, heat pump pool heaters can last 10 or more years.¹⁵ For Type 1 pool heaters, the analysis assumes a 15-year useful life and four percent discount rate and thus a PVF of 11.118, as calculated per Equation 2-2, and the estimated cost for an electrical panel upgrade of \$2,500. If splitting the panel cost between pool heating and other residential appliances, the panel cost is

¹³ U.S. Department of Energy, Tankless or Demand-Type Water Heaters, <https://www.energy.gov/energysaver/tankless-or-demand-type-water-heaters>

¹⁴ South Coast AQMD, 2022 AQMP, <https://www.aqmd.gov/docs/default-source/clean-air-plans/air-quality-management-plans/2022-air-quality-management-plan/final-2022-aqmp/appendix-iv-a.pdf?sfvrsn=18>

¹⁵ U.S. Department of Energy, Heat Pump Swimming Pool Heaters, <https://www.energy.gov/energysaver/heat-pump-swimming-pool-heaters>

$\$2,500 \div 4 = \625 . The analysis also utilizes the residential utility rate forecast for Type 1 pool heaters.

Type 1 and Type 2 High Temperature Units

Meetings and site visits with manufacturers during the rulemaking process indicated a useful life of under and over 25 years for gas-fired boilers, or high temperature units. For Type 1 and Type 2 high temperature units, the analysis assumes a 25-year useful life and four percent discount rate and thus a PVF of 15.622, as calculated per Equation 2-2, and the estimated cost for an electrical panel upgrade of \$4,200.

Instantaneous Water Heaters

U.S. DOE estimates a useful life of more than 20 years for instantaneous water heaters.¹⁶ For instantaneous water heaters, the analysis assumes a 25-year useful life and four percent discount rate and thus a PVF of 15.622, as calculated per Equation 2-2, and the estimated cost of an electrical panel upgrade of \$4,200. If splitting the panel cost between pool heating and other residential appliances, the panel cost is $\$4,200 \div 4 = \$1,050$.

Estimating Fuel Switching Cost

The analysis considered the cost impacts of transitions from conventional combustion heating that uses natural gas to zero-emission technologies that use electricity as part of the cost-effectiveness assessment. For this assessment, the analysis relied upon the fuel price estimates which are based on a combination of CEC's 2023 Integrated Energy Policy Report and Energy Information Administration (EIA) national level forecasts. The current CEC forecast extends to 2050. Electricity forecasts are based on the Los Angeles Department of Water and Power (LADWP) and Southern California Edison (SCE) planning areas. Natural gas forecasts are only based on Southern California Gas company forecasts, as Southern California Gas company is the primary gas utility in the region. Forecasted prices will not match observed electric and natural gas prices in any given year and may differ materially. Current prices are affected by demand and supply shocks, geopolitical factors, and other considerations which are all unforecastable. However, the CEC forecasts are created through a rigorous modeling process and reflect the best available expectation for future prices in the region. CEC forecasts are released every two years.

The analysis utilizes the residential utility rate forecast for Type 1 pool heaters and instantaneous water heaters, and commercial utility rate forecast for other units.

Since the forecasted prices for LADWP and SCE differ, staff calculated a weighted average price based on the population served by each utility as follows:

- LADWP: $4 \text{ million} \div 17.2 \text{ million (Population served by LADWP} \div \text{regional population)} = 0.23$
- SCE: $13.2 \text{ million} \div 17.2 \text{ million} = 0.77$

To estimate the fuel switching cost by category for replacement of natural gas-fired units with zero-emission technology, the analysis:

¹⁶ U.S. Department of Energy, Tankless or Demand-Type Water Heaters,
<https://www.energy.gov/energysaver/tankless-or-demand-type-water-heaters>

1. Estimated the daily electricity demand (in kWh) of the electric unit which will be replacing the existing natural gas fired unit;
2. Estimated the daily natural gas demand (in therms) of the existing natural gas fired unit;
3. Multiplied the daily demand for each fuel type by the number of operating days in a year to estimate the annual energy demand of each unit;
4. Multiplied the annual energy demand in each year and for each fuel type by the forecasted price of each fuel in that year to estimate the annual fuel cost for each unit;
5. Netted the difference between the total electricity cost and total natural gas cost to estimate incremental fuel switching cost in each year.

The list of steps explains the process to estimate switching costs of a single unit. The analysis also utilized a bottom-up calculation with individual units that fill similar roles from different categories. The daily electricity and natural gas demand values were estimated by the following approaches, where applicable.

Energy Input Estimate Method

With this method, the fuel switching costs for electric replacement units were estimated based on electric input values (kWh) provided by the unit manufacturer.

Energy Input Calculation Method

For situations where the energy input was not provided by a unit manufacturer, an alternate, more conservative method than the Energy Input Estimate Method was relied upon to calculate fuel switching cost, which is referred to here as the “Energy Input Calculation Method.” There are certain factors that this alternate method does not take into account. For example, while the Energy Input Calculation Method assumes the same amount of energy output for the gas unit and electric replacement unit via hot water, the oversizing of heat pumps replacing gas-fired units and cycling losses may not be represented. To calculate daily kWh input:

$$\text{Gas Unit Rating in Btu/hr} \times 24 \text{ hours} \times \text{Gas Unit Capacity Factor} \div 3,412.14 \text{ Btu/kWh} \times \\ \text{Gas Unit Efficiency} \div \text{COP Heat Pump Efficiency}$$

Equation 2-4. Energy Input Calculation Method Equation

Note that 1 kWh = 3,412.14 Btu.

Cost and Cost-Effectiveness

Cost-Effectiveness Screening Threshold

The 2022 AQMP established a cost-effectiveness screening threshold of \$325,000 per ton of NO_x reduced based on 2021 dollars. The 2022 AQMP stated that this screening threshold will be adjusted based on the annual California Consumer Price Index (CPI). PAR 1146.2 currently considers a \$349,000 per ton of NO_x reduced cost-effectiveness screening threshold using 2022 dollars. The 2022 AQMP threshold is neither considered a starting point for control costs, nor an absolute cap.

Type 1 Water Heater

The analysis considered the potential replacement of a 76,000 Btu/hr natural gas-fired Type 1 water heater with a zero-emission heat pump water heater. The capital cost for a natural gas-fired

unit is estimated at \$7,000, which was derived from the Rule 1146.2 May 2006 final staff report which estimated the cost for a unit with a heat rating ranging from 100,000 to 300,000 Btu/hr and adjusted to present value by the CPI Inflation Calculator. A manufacturer provided the capital cost of \$11,000 for a zero-emission indoor packaged commercial heat pump unit with a COP of 4.2. The annual energy input of 5,841 kWh was provided by the manufacturer for the unit. The unit water use is 350 gallons per day.¹⁷ Adding an additional 20 percent to the zero-emission unit cost to address installation cost results in \$13,200 for the zero-emission unit.

By applying the Energy Input Estimate Method, the calculation for kWh of daily energy input is $5,841 \text{ kWh} \div 365 \text{ days} = 16 \text{ kWh daily input}$. Fuel switching cost savings are \$11,000. In terms of cost-effectiveness, without a panel upgrade, there are cost savings of \$190,000 per ton of NOx reduced; with a panel upgrade, cost savings are \$93,000 per ton of NOx reduced.

For contrast, by applying the Energy Input Calculation Method, the calculation for kWh of daily energy input is $76,000 \text{ Btu/hr} \times 24 \text{ hours} \times 0.215 \text{ capacity factor} \times 0.95 \text{ natural gas-fired unit efficiency} \div 3412.14 \text{ Btu/kWh} \div 4.2 \text{ heat pump COP} = 26 \text{ kWh daily input}$. Fuel switching cost savings is \$1,000. In terms of cost-effectiveness, without a panel upgrade, there is a cost of \$201,000 per ton of NOx reduced; with a panel upgrade, the cost is \$298,000 per ton of NOx reduced.

Type 2 Water Heater

Type 2 Water Heater Scenario 1: Replacement with Six Integrated Heat Pumps

The analysis considered the potential replacement of a 500,000 Btu/hr natural gas-fired Type 2 water heater with six 76,000 Btu/hr zero-emission integrated heat pump water heaters. The capital cost for a natural gas-fired commercial tank type high efficiency unit is estimated at \$14,000, which was derived from the Rule 1146.2 May 2006 final staff report which estimated the cost for a unit with a heat rating ranging from 400,000 to 500,000 Btu/hr and adjusted to present value by the CPI Inflation Calculator. The analysis also considered a case presented by an installer where two 500,000 Btu/hr units were replaced with seven integrated heat pumps. In this case, the second 500,000 Btu/hr unit and the seventh heat pump were for redundancy purposes, so the analysis considered the replacement of one 500,000 Btu/hr natural gas-fired unit with six zero-emission heat pumps. A manufacturer provided the capital cost of \$11,000 for one zero-emission indoor packaged commercial integrated heat pump unit with a COP of 4.2; the capital cost for the six zero-emission heat pumps is \$66,000, which is the cost of the individual heat pump multiplied by six. The annual energy input of 5,841 kWh was provided by the manufacturer for one unit. Adding an additional 20 percent to the zero-emission unit cost to address installation cost results in \$79,200 for the zero-emission units.

By applying the Energy Input Estimate Method, the calculation for kWh of daily energy input is $5,841 \text{ kWh} \div 365 \text{ days} \times 6 \text{ units} = 96 \text{ kWh daily input}$. Fuel switching cost savings are \$116,000. In terms of cost-effectiveness, without a panel upgrade, the cost savings will be \$178,000 per ton of NOx reduced; with a panel upgrade, the cost savings will be \$164,000 per ton of NOx reduced.

By applying the Energy Input Calculation Method, the calculation for kWh of daily energy input is $500,000 \text{ Btu/hr} \times 24 \text{ hours} \times 0.215 \text{ capacity factor} \times 0.95 \text{ natural gas-fired unit efficiency} \div 3412.14 \text{ Btu/kWh} \div 4.2 \text{ heat pump COP} = 171.03 \text{ kWh daily input}$. Fuel switching cost savings

¹⁷ AO Smith, <https://assets.hotwater.com/damroot/Original/10003/AOSZE55000.pdf>

are \$9,000. In terms of cost-effectiveness, without a panel upgrade, the cost is \$197,000 per ton of NOx reduced; with a panel upgrade, the cost is \$212,000 per ton of NOx reduced.

Type 2 Water Heater Scenario 2: Replacement with Two Split Heat Pumps

A major manufacturer recommended a different replacement case for Type 2 water heaters and recommended replacing one 500,000 Btu/hr natural gas-fired unit with two large split heat pumps with a COP of 4.38 paired with a 400-gallon tank for an anticipated capital cost of \$70,000.¹⁸ Adding an additional 20 percent to the zero-emission unit cost to address installation cost results in \$84,000 for the zero-emission unit. Capital cost for the natural gas-fired commercial tank type high efficiency unit is estimated at \$14,000, taken from the Rule 1146.2 May 2006 staff report estimated cost for the 400,000-500,000 Btu/hr unit range and adjusted to present value by the CPI Inflation Calculator.

The energy input (kWh) for this scenario was not provided by the manufacturer, so the analysis did not apply the Energy Input Estimate Method. By applying the Energy Input Calculation Method, the calculation for kWh of daily energy input is $500,000 \text{ Btu/hr} \times 24 \text{ hours} \times 0.215 \text{ capacity factor} \div 0.95 \text{ natural gas-fired unit efficiency} \div 3412.14 \text{ Btu/kWh} \div 4.38 \text{ heat pump COP} = 164 \text{ kWh daily input}$. Fuel switching cost savings are \$19,000. In terms of cost-effectiveness, without a panel upgrade, the cost is \$179,000 per ton of NOx reduced; with a panel upgrade, the cost is \$194,000 per ton of NOx reduced.

Scenario 2 provides a cost-effectiveness value estimate less than the 2022 AQMP cost-effectiveness screening threshold of \$349,000 per ton of NOx reduced. Scenario 2 has a slightly higher capital cost of \$4,800 greater than Scenario 1.

Type 1 Pool Heater

The analysis considered the potential replacement of a 125,000 Btu/hr natural gas-fired pool heater with a 90,000 Btu/hr zero-emission heat pump pool heater. As of December 2023, an internet search for a 125,000 Btu/hr natural gas-fired unit indicated that the capital cost is \$1,800.¹⁹ The table below presents other natural gas water heater cost examples obtained via an internet search. For example, as of December 2023, an internet search for a 90,000 Btu/hr zero-emission heat pump indicated that the capital cost is \$4,100.²⁰ The heat pump has a COP of 5.7. Adding an additional 20 percent to the zero-emission unit cost to address installation cost results in \$4,920 for the zero-emission unit.

¹⁹ In the Swim, <https://intheswim.com/p/ec-462024-mastertemp-low-nox-125k-btu-natural-gas-pool-spa-heater-with-cord---limited-warranty/387225.html>

²⁰ In the Swim, <https://intheswim.com/p/w3hp21004t-heatpro-90k-btu-230v-titanium-digital-electric-pool-heat-pump/340101.html>

Table 2-4. Natural gas water heater cost examples from internet search

Heat Output Btu/hr	Price (\$)	Heat Output Btu/hr	Price (\$)	Heat Output Btu/hr	Price (\$)
105,000	2,000	206,000	2,000	300,000	4,000
125,000	2,000	240,000	3,000	333,000	4,000
156,000	2,000	264,000	3,000	360,000	4,000
180,000	3,000	266,000	3,000	404,000	4,000

By applying the Energy Input Calculation Method, the calculation for kWh of daily energy input is $125,000 \text{ Btu/hr} \times 24 \text{ hours} \times 0.024 \text{ capacity factor} \times 0.84 \text{ natural gas-fired unit efficiency} \div 3412.14 \text{ Btu/kWh} \div 5.7 \text{ heat pump COP} = 3.11 \text{ kWh daily input}$. Fuel switching cost savings are \$3,000. In terms of cost-effectiveness, without a panel upgrade, the cost is \$11,000 per ton of NOx reduced; with a panel upgrade, the cost is \$58,000 per ton of NOx reduced. When splitting the panel cost between residential appliances, with a quarter of the panel cost for pool heating, the cost-effectiveness estimate is cost savings of \$4,000 per ton of NOx reduced.

Type 1 High Temperature Unit

Type 1 High Temperature Unit Scenario 1: Replacement with Heat Pump Unit

The analysis considered the potential replacement of a 399,000 Btu/hr natural gas-fired Type 1 boiler with a 365,000 Btu/hr heat pump. A manufacturer provided a capital cost of \$24,000 for a 399,000 Btu/hr natural gas-fired Type 1 boiler. A manufacturer provided a capital cost to consumer of \$185,000 for a 365,000 Btu/hr heat pump using waste heat with a COP of 6.3.²¹ Adding an additional 20 percent to the zero-emission unit cost to address installation cost results in \$222,000 for the zero-emission unit.

The energy input (kWh) for this scenario was not provided by the manufacturer, so the analysis did not apply the Energy Input Estimate Method. By applying the Energy Input Calculation Method, the calculation for kWh of daily energy input is $399,000 \text{ Btu/hr} \times 24 \text{ hours} \times 0.215 \text{ capacity factor} \times 0.95 \text{ natural gas-fired unit efficiency} \div 3412.14 \text{ Btu/kWh} \div 6.3 \text{ heat pump COP} = 90.99 \text{ kWh daily input}$. Fuel switching cost savings are \$72,000. In terms of cost-effectiveness, without a panel upgrade, the cost is \$559,000 per ton of NOx reduced; with a panel upgrade, there is a cost of \$578,000 per ton of NOx reduced.

Type 1 High Temperature Unit Scenario 2: Replacement with Electric Resistance Unit

The analysis considered replacement of a 399,000 Btu/hr natural gas-fired Type 1 boiler with a 358,000 Btu/hr electric boiler. A manufacturer provided a capital cost of \$24,000 for a 399,000 Btu/hr natural gas-fired Type 1 boiler. As of December 2023, an internet search for a 358,000 Btu/hr electric resistance boiler indicated that the capital cost is \$25,000.²² The analysis also assumed a 100 percent efficiency for electric resistance units. Adding an additional 20 percent to

²¹ Armstrong International, Inc., <https://armstronginternational.com/products/armstrongcombitherm-heat-pumps/>

²² ecomfort, <https://www.ecomfort.com/Electro-Industries-EB-NB-105-208/p18338.html>

the zero-emission unit cost to address installation cost results in \$30,000 for the zero-emission unit.

The energy input (kWh) for this scenario was not provided by the manufacturer, so the analysis did not apply the Energy Input Estimate Method. By applying the Energy Input Calculation Method, the calculation for kWh of daily energy input is $399,000 \text{ Btu/hr} \times 24 \text{ hours} \times 0.215 \text{ capacity factor} \times 0.95 \text{ natural gas-fired unit efficiency} \div 3412.14 \text{ Btu/kWh} = 573.22 \text{ kWh daily input}$. Fuel switching cost is \$610,000. In terms of cost-effectiveness, without a panel upgrade, the cost is \$2,734,000 per ton of NOx reduced; with a panel upgrade, the cost is \$2,753,000 per ton of NOx reduced.

Type 2 High Temperature Unit

Type 2 High Temperature Unit Scenario 1: Replacement of 1 MMBtu Unit with Heat Pump

The analysis considered the potential replacement of a 1 MMBtu/hr natural gas-fired Type 2 boiler with a 1,709,000 Btu/hr heat pump. A manufacturer provided a capital cost of \$32,500 for a 1 MMBtu/hr natural gas-fired Type 2 boiler. A manufacturer provided a capital cost to consumer of \$280,000 for a 1,709,000 Btu/hr heat pump using waste heat with a COP of 5.9. Adding an additional 20 percent to the zero-emission unit cost to address installation cost results in \$336,000 for the zero-emission unit.

The energy input (kWh) for this scenario was not provided by the manufacturer, so the analysis did not apply the Energy Input Estimate Method. By applying the Energy Input Calculation Method, the calculation for kWh of daily energy input is $1 \text{ MMBtu/hr} \times 24 \text{ hours} \times 0.215 \text{ capacity factor} \times 0.95 \text{ natural gas-fired unit efficiency} \div 3412.14 \text{ Btu/kWh} \div 5.9 \text{ heat pump COP} = 243.5 \text{ kWh daily input}$. Fuel switching cost savings are \$158,000. In terms of cost-effectiveness, without a panel upgrade, there is a cost of \$257,000 per ton of NOx reduced; with a panel upgrade, the cost is \$264,000 per ton of NOx reduced.

Type 2 High Temperature Unit Scenario 2: Replacement of 1 MMBtu Unit with Electric Resistance

The analysis considered replacement of a 1 MMBtu/hr natural gas-fired Type 2 boiler with a 1 MMBtu/hr electric boiler. A manufacturer provided a capital cost of \$32,500 for a 1 MMBtu/hr natural gas-fired Type 2 boiler. As of December 2023, an internet search for a 1 MMBtu/hr electric resistance boiler indicated that the capital cost is \$34,000.²³ Adding an additional 20 percent to the zero-emission unit cost to address installation cost results in \$40,800 for the zero-emission unit.

The energy input (kWh) for this scenario was not provided by the manufacturer, so the analysis did not apply the Energy Input Estimate Method. By applying the Energy Input Calculation Method, the calculation for kWh of daily energy input is $1 \text{ MMBtu/hr} \times 24 \text{ hours} \times 0.215 \text{ capacity factor} \times 0.95 \text{ natural gas-fired unit efficiency} \div 3412.14 \text{ Btu/kWh} = 1,436.64 \text{ kWh daily input}$. Fuel switching cost is \$1,530,000. In terms of cost-effectiveness, without a panel upgrade, there is a cost of \$2,722,000 per ton of NOx reduced; with a panel upgrade, there is a cost of \$2,812,000 per ton of NOx reduced.

²³ ecomfort, <https://www.ecomfort.com/Electro-Industries-EB-NB-300-480/p18335.html>

Type 2 Boiler Scenario 3: Replacement of 2 MMBtu Unit with Heat Pump

The analysis considered the replacement of a 2 MMBtu/hr natural gas-fired Type 2 boiler with a 2,286,000 Btu/hr heat pump. A manufacturer provided a capital cost of \$43,500 for a 2 MMBtu/hr natural gas-fired Type 2 boiler. A manufacturer provided a capital cost to consumer of \$462,000 for a 2,286,000 Btu/hr heat pump using waste heat with a COP of 6.1. Adding an additional 20 percent to the zero-emission unit cost to address installation cost results in \$554,400 for the zero-emission unit.

The energy input (kWh) for this scenario was not provided by the manufacturer, so the analysis did not apply the Energy Input Estimate Method. By applying the Energy Input Calculation Method, the calculation for kWh of daily energy input is $2 \text{ MMBtu/hr} \times 24 \text{ hours} \times 0.215 \text{ capacity factor} \times 0.95 \text{ natural gas-fired unit efficiency} \div 3412.14 \text{ Btu/kWh} \div 6.1 \text{ heat pump COP} = 471.03 \text{ kWh daily input}$. Fuel switching cost savings are \$339,000. In terms of cost-effectiveness, without a panel upgrade, there is a cost of \$152,000 per ton of NOx reduced; with a panel upgrade, there is a cost of \$156,000 per ton of NOx reduced.

Instantaneous Water Heater

Instantaneous Water Heater Scenario 1: Replacement with Electric Resistance Tank Type Unit

The analysis assumed that a 150,000 Btu/hr natural gas-fired instantaneous water heater could be replaced with a 75-gallon electric resistance tank type unit. The analysis also assumed that the installation cost would be approximately 25 percent of the project cost. Drawing from an E3 study, the natural gas-fired unit capital cost is $\$3,700 \times 0.75 = \$2,775$ for a 150,000 Btu/hr instantaneous water heater.²⁴ As of December 2023, an internet search for a 75-gallon electric resistance tank type unit indicated that the capital cost is \$2,100.²⁵ Adding an additional 20 percent to the zero-emission unit cost to address installation cost results in \$2,520 for the zero-emission unit.

The energy input (kWh) for this scenario was not provided by the manufacturer, so the analysis did not apply the Energy Input Estimate Method. By applying the Energy Input Calculation Method, the calculation for kWh of daily energy input is $150,000 \text{ Btu/hr} \times 24 \text{ hours} \times 0.0135 \text{ capacity factor} \times 0.95 \text{ natural gas-fired unit efficiency} \div 3412.14 \text{ Btu/kWh} = 13.53 \text{ kWh daily input}$. Fuel switching cost is \$17,000. In terms of cost-effectiveness, without a panel upgrade, there is a cost of \$3,078,000 per ton of NOx reduced; with a panel upgrade, there is a cost of \$3,275,000 per ton of NOx reduced.

Instantaneous Water Heater Scenario 2: Replacement with Electric Resistance Instantaneous Unit

The analysis assumed that a 150,000 Btu/hr natural gas-fired instantaneous water heater could be replaced by an electric resistance instantaneous unit. The analysis assumed that installation cost is approximately 25 percent of the project cost. Drawing from the E3 study, the natural gas-fired unit capital cost is $\$3,700 \times 0.75 = \$2,775$ for a 150,000 Btu/hr instantaneous water heater. As of December 2023, an internet search for an electric resistance instantaneous unit indicated that the

²⁴ E3, Residential Building Electrification in California, Page 32, Figure 2-7, https://www.ethree.com/wp-content/uploads/2019/04/E3_Residential_Building_Electrification_in_California_April_2019.pdf

²⁵ The Home Depot, <https://www.homedepot.com/p/Rheem-Marathon-Eclipse-Light-Duty-75-gal-Commercial-277-Volt-12kW-Field-Convertible-Non-Metallic-Electric-Water-Heater-MELD75-TB-277-Volt-12-kW/305422236>

higher end capital cost is \$2,300.²⁶ Adding an additional 20 percent to the zero-emission unit cost to address installation cost results in \$2,760 for the zero-emission unit.

The energy input (kWh) for this scenario was not provided by the manufacturer, so the analysis did not apply the Energy Input Estimate Method. By applying the Energy Input Calculation Method, the calculation for kWh of daily energy input is $150,000 \text{ Btu/hr} \times 24 \text{ hours} \times 0.0135 \text{ capacity factor} \times 0.95 \text{ natural gas-fired unit efficiency} \div 3412.14 \text{ Btu/kWh} = 13.53 \text{ kWh daily input}$. Fuel switching cost is \$17,000. In terms of cost-effectiveness, without a panel upgrade, there is a cost of \$3,123,000 per ton of NOx reduced; with a panel upgrade, there is a cost of \$3,320,000 per ton of NOx reduced.

Instantaneous Water Heater Scenario 3: Replacement with Heat Pump Tank

Type Unit

The analysis assumed that a 150,000 Btu/hr natural gas-fired instantaneous water heater could be replaced with a residential 65-gallon storage volume heat pump with a COP of 3.0. The analysis also assumed that the installation cost is approximately 25 percent of the project cost. Drawing from an E3 study, the natural gas-fired unit capital cost is $\$3,700 \times 0.75 = \$2,775$ for a 150,000 Btu/hr instantaneous water heater. Energy Star by U.S. EPA provided information on a 64-gallon storage volume heat pump with a Uniform Energy Factor of 3.64, which has a capital cost of around \$2,000 from internet search.²⁷ Energy Star provides 178 therms per year for instantaneous and 1,233 kwh for an equivalent heat pump. Adding an additional 20 percent to the zero-emission unit cost to address installation cost results in \$2,400 for the zero-emission unit.

By applying the Energy Input Estimate Method, the calculation for kWh of daily energy input is $1,233 \text{ kWh} \div 365 \text{ days} = 3.4 \text{ kWh daily input}$. Fuel switching cost is cost savings of \$600. In terms of cost-effectiveness, without a panel upgrade, cost savings are \$185,000 per ton of NOx reduced; with a panel upgrade, the cost is \$12,000 per ton of NOx reduced.

When splitting the panel cost between residential appliances, with a quarter of the panel cost for pool heating, the cost-effectiveness estimate is cost savings of \$63,000.

By applying the Energy Input Calculation Method, the calculation for kWh of daily energy input is $150,000 \text{ Btu/hr} \times 24 \text{ hours} \times 0.0135 \text{ capacity factor} \times 0.95 \text{ natural gas-fired unit efficiency} \div 3412.14 \text{ Btu/kWh} \div 3.0 \text{ heat pump COP} = 4.51 \text{ kWh daily input}$. Fuel switching cost is \$1,000. In terms of cost-effectiveness, without a panel upgrade, there is a cost of \$101,000 per ton of NOx reduced; with a panel upgrade, there is a cost of \$298,000 per ton of NOx reduced.

When splitting the panel cost between residential appliances, with a quarter of the panel cost for pool heating, the cost-effectiveness estimate is cost of \$223,000 per ton of NOx reduced.

When applying the Energy Input Calculation Method for gas-fired instantaneous units replaced by heat pumps, there is a higher energy input (kWh) and higher fuel switching cost which may result from oversizing. The energy input (kWh) may be overestimated.

Summary of Cost-Effectiveness

The following table summarizes the cost-effectiveness estimates for each category.

Table 2-5. Cost-Effectiveness for PAR 1146.2 Categories

Category	Replace with	Cost-Effectiveness (\$/Ton), No Panel Upgrade		Cost-Effectiveness (\$/Ton), With Panel Upgrade	
		Energy Input Estimate Method	Energy Input Calculation Method	Energy Input Estimate Method	Energy Input Calculation Method
Type 1 Water Heater	Heat Pump	(190,000)	201,000	(93,000)	298,000
Type 2 Water Heater	Six Heat Pumps (Integrated)	(178,000)	197,000	(164,000)	212,000
	Two Heat Pumps (Split)	-	179,000	-	194,000
Type 1 Pool Heater	Heat Pump	-	11,000	-	58,000
	Heat Pump and Split Panel Cost	-		-	(4,000)
Type 1 High Temperature Unit	Heat Pump	-	559,000	-	578,000
	Electric Resistance	-	2,734,000	-	2,753,000
Type 2 High Temperature Unit (1 MMBtu/hr)	Heat Pump	-	257,000	-	264,000
	Electric Resistance	-	2,722,000	-	2,812,000
Type 2 High Temperature Unit (2 MMBtu/hr)	Heat Pump	-	152,000	-	156,000

Category	Replace with	Cost-Effectiveness (\$/Ton), No Panel Upgrade		Cost-Effectiveness (\$/Ton), With Panel Upgrade	
		Energy Input Estimate Method	Energy Input Calculation Method	Energy Input Estimate Method	Energy Input Calculation Method
Instantaneous Water Heater	Heat Pump	(185,000)	101,000	12,000	298,000
	Heat Pump and Split Panel Cost	-	-	(63,000)	223,000
	Electric Resistance Tank Type	-	3,078,000	-	3,275,000
	Electric Resistance Instantaneous	-	3,123,000	-	3,320,000

The cost-effectiveness values for most categories in PAR 1146.2 were less than the \$349,000 per ton of NO_x screening threshold; thus, zero-emission (0 ppmv) technologies are considered cost-effective. While some cost-effectiveness values are greater than the 2022 AQMP screening threshold of \$349,000 per ton of NO_x reduced, future effective compliance dates will allow for market growth in the next 10 years. Market growth for emerging technologies typically includes a price decrease. Currently, the market supply is limited and some of the zero-emission units staff evaluated require preplanning and adjustment prior to installation, which will involve a considerably higher cost. Once more units are commercialized and sold as off-the-shelf units, staff expect costs to drop. Staff is proposing to conduct a technology assessment prior to the implementation of the zero-emission units that had a high cost-effectiveness and will reassess costs at that time.

Proposed BARCT Emission Limit

Health and Safety Code Section Sections 40920.6(a)(1) and 40920.6(a)(2) require that prior to adopting rules to meet the requirement of BARCT, one or more potential control options which achieve the emission reduction objectives of the rule must be identified and the cost-effectiveness assessment of the potential control option(s) must be conducted. The final proposed BARCT emission limit for each class and category is the emission limit that achieves the maximum degree of emission reductions and is determined to be cost-effective.

The following table summarizes the proposed NO_x limits that represent BARCT and the applicable CO limits for each class and category. The zero-emission technologies staff evaluated operate on electricity and have zero CO emissions in addition to zero NO_x emissions; hence, staff is proposing zero-emission limits for both pollutants.

Table 2-6. Proposed BARCT NO_x and CO Emission Limits, Compliance Schedule, and Unit Age

Equipment Category	NO _x and CO Emission Limits (ppmv)	Building Type	Compliance Date	Unit Age (years)
Type 1 Unit*	0	New	January 1, 2026	15
		Existing	January 1, 2029	
Instantaneous Water Heater ≤ 200,000 Btu/hr	0	New	January 1, 2026	25
		Existing	January 1, 2029	
Instantaneous Water Heater > 200,000 Btu/hr	0	New	January 1, 2028	25
		Existing	January 1, 2031	
Type 1 Pool Heater	0	New	January 1, 2028	15
		Existing	January 1, 2031	
Type 2 Unit**	0	New	January 1, 2028	25
		Existing	January 1, 2031	
Type 1 High Temperature Unit	0	New	January 1, 2029	25
		Existing	January 1, 2033	
Type 2 High Temperature Unit	0	New	January 1, 2029	25
		Existing	January 1, 2033	

* Referring to a Type 1 unit that is not a high temperature unit, pool heater, or instantaneous water heater.

** Referring to a Type 2 unit that is not a high temperature unit or instantaneous water heater.

Future implementation dates will allow for an increase in the supply of zero-emission technology in the market. Manufacturers are already producing heat pumps and may adjust business operations based on policy direction and market conditions. There is an expectation for the supply chain to adjust to changing market conditions. Furthermore, staff is proposing to require the zero-emissions technologies at end of unit age, with unit expected age of potentially 15 to 25 years depending on the type of unit; therefore, staff does not expect a sudden peak in demand. PAR 1146.2 proposes longer timeframes for end-of-unit-age replacements in existing buildings versus installations in new buildings and also proposes zero-emission limits for retrofits and burner modification after the proposed compliance dates.

Some of the proposed emission limits for some of the equipment categories subject to PAR 1146.2 are considered technology-forcing, meaning the emission limits are based on a technology that is not widely commercially available at the time of amending the rule. When South Coast AQMD adopts rules with technology-forcing emission limits, the limits are given a future implementation date to allow time for the technology to develop. BARCT limits evolve over time as the technology

improves or new pollution control technologies emerge; setting future effective emission limits is an approach that has been used and upheld in other rules. For example, South Coast AQMD adopted VOC limits in Rule 1113 – Architectural Coatings in 2002 with a future effective date of July 1, 2006, based on emerging technology (e.g., reformulated coatings). The technology to meet the lower VOC limits was commercially available at the time of rule development but had performance issues that had yet to be overcome. The American Coatings Association sued the South Coast AQMD for adopting technology-forcing BARCT limits, but the South Coast AQMD prevailed in the Supreme Court of California, which upheld the ability to adopt technology-forcing BARCT limits. Furthermore, staff will include a requirement to conduct a technology assessment prior to the zero-emission compliance dates.

Staff proposes to conduct a technology assessment, which will be included as part of the Governing Board resolution adopting PAR 1146.2. The technology assessment would assess any change in capital cost or technology development for certain high temperature applications; assess any change in cost-effectiveness for certain categories; and monitor market supply and growing opportunities for contractor training. Staff will also reassess the fuel switching costs. Utility rates tend to fluctuate over time and are difficult to predict, so an evaluation of utility rates would be appropriate. The technology assessment will evaluate the status of zero-emission technology for all equipment categories and address any equity issues.

ADDITIONAL BENEFITS AND CHALLENGES

Electric Grid Infrastructure

In 2021, renewable generation accounted for 33.6 percent of the total California Power Mix, not including solar photovoltaic systems installed on residential and commercial buildings that are less than one megawatt (MW) as they are typically considered distributed generation and not required to report to CEC.²⁸ The California Power Mix is the percentage of specified fuel types derived from the California Energy Mix, and the California Energy Mix is the total in-state electric generation plus energy imports. There is expected to be more renewables adoption by states in the future, and California Senate Bill 100 called for a Renewables Portfolio Standard of 60 percent by 2030. Electricity imports account for approximately 30 percent of total system electric generation, with other states pursuing Renewable Portfolio Standards and state energy goals.

The CEC, California Public Utilities Commission (CPUC), and CARB are working to coordinate across efforts, identify issues not covered by ongoing efforts, and assess needed actions to better align the energy system with the state's climate targets. Related initiatives include the CPUC's proceeding to support decarbonizing buildings in California (R.19-01-011), which eliminated gas line extension subsidies for new gas hookups to homes and commercial buildings effective July 1, 2023.²⁹ In February 2023, the CPUC ordered load serving entities to procure an additional 4,000 MW of Net Qualifying Capacity for 2026 and 2027, in addition to the mid-term reliability procurement requirements ordered in 2021 (11,500 MW, enough to power approximately 2.5 million homes). The CPUC also approved four energy storage contracts totaling 372 MW for SCE and recommended an electric resource portfolio for use in the California Independent System

²⁸ California Energy Commission, 2021 Total System Electric Generation, <https://www.energy.ca.gov/data-reports/energy-almanac/california-electricity-data/2021-total-system-electric-generation>

²⁹ California Public Utilities Commission, Press Release, <https://docs.cpuc.ca.gov/PublishedDocs/Published/G000/M496/K979/496979465.PDF>

Operator's (CAISO) 2023-24 Transmission Planning Process. The recommended portfolio includes over 85 gigawatts (GW) of new resources by 2035, including 54,000 MW of renewable resources; over 28,000 MW of batteries; 2,000 MW of long-duration storage; and 1,100 MW of demand response.

The CEC adopts an Integrated Energy Policy Report (IEPR) every two years and an update every other year. The 2022 IEPR has recognized the proposed zero-emission requirements for residential and commercial buildings in California and included recommendations and updates to the energy demand forecast.³⁰ The IEPR update released on January 1, 2024, provided forecasts for future natural gas and electricity rates, which staff utilized in the cost-effectiveness analysis. Staff used the cost averages for the period of 2024 – 2050, which are \$1.71 per therm or 5.84 cents/kWh for natural gas and 24.81 cents/kWh for electricity commercial rates. For residential rates, used for Type 1 pool heaters and instantaneous water heaters, staff used the cost averages for the period of 2024 – 2050, which are \$2.31 per therm or 7.88 cents/kWh for natural gas and 29.85 cents/kWh for electricity. Previously, staff relied on 2021 IEPR for PAR 1146.2 cost effectiveness assessment. The update impacted the cost estimates to switch from natural gas-fired units to heat pumps, as the newest IEPR projected the natural gas rate to increase 40% and electricity rate to have a more moderate increase of 28%. This resulted in a decrease in cost-effectiveness estimates from the initial assessment due to the increase in cost savings from fuel switching.

Under Assembly Bill 3232 (Friedman, Chapter 373, Statutes of 2018), the CEC must assess the feasibility of reducing greenhouse gas emissions in residential and commercial buildings 40 percent below 1990 levels by January 1, 2030. Statewide electricity consumption was over 280,000 GWh in 2021 and is forecasted to be 358,738 GWh in 2035. The 2022 Planning Scenario peak forecast for CAISO, which manages roughly 80 percent of California's load, reaches 55,117 MW by 2035. CAISO is planning \$11 billion in transmission capacity projects over the next 20 years, which covers 80 percent of the entire state service area. The 20-Year Transmission Outlook document from May 2022 considers transmission needs to meet load and renewable energy growth aligned with state policy. The plan describes \$11 billion in upgrades to the existing CAISO transmission footprint.³¹ In addition, solar photovoltaic generation continues to increase as shown in the figure below.³² Between 2022 and 2035, behind-the-meter photovoltaic generation is expected to grow on average by about six percent, reaching annual photovoltaic generation of 55,740 GWh by 2035.

Figure 2-4-5. In-State Electric Generation – Select Fuel Types, Sourced from CEC Quarterly Fuels and Energy Reporting Regulations

According to SCE’s 2021 Sustainability Report, SCE is expected to invest over \$5 billion annually in the electric grid, with approximately 3,400 MW of energy storage installed or contracted. In 2021, SCE procured 530 MW of energy storage through three new contracts from third parties and in the same year, entered into an engineering, procurement, and construction agreement to construct approximately 535 MW of utility-owned storage. SCE also expected increases in Distributed Energy Resources such as residential solar.³³ In the Pathway to 2045 document, SCE expected a 60 percent increase in electricity load and 40 percent increase in peak load by 2045, with building electrification responsible for 15 percent of load by 2045. SCE noted that the grid will still be summer peaking due to air conditioning.³⁴

Staff recognizes the importance of electric grid reliability for electric units, but also for natural gas units, which often require electricity to operate. In 2021, the CPUC created new programs and modified existing programs to reduce energy demand and increase energy supply during critical hours of the day.³⁵ Per Senate Bill 350 (De León, 2015), the CPUC developed an integrated resource planning process to ensure that California’s electric sector meets its greenhouse gas reduction goals while maintaining reliability at the lowest possible costs.³⁶ Staff recognizes that there are externalities for both electric and natural gas production and distribution. Staff also

³⁶ California Public Utilities Commission, CPUC Approves Long Term Plans To Meet Electricity Reliability and Climate Goals, <https://www.cpuc.ca.gov/news-and-updates/all-news/cpuc-approves-long-term-plans-to-meet-electricity-reliability-and-climate-goals>

recognizes the need for regulation of emissions from electricity generation. South Coast AQMD Rule 1135 – Emissions of Oxides of Nitrogen from Electricity Generating Facilities, is a rule that aims to lower emissions from electricity generation.³⁷ Regarding the natural gas system, natural gas leaks into the atmosphere from natural gas wells, storage tanks, pipelines, and processing plants. In 2020, methane emissions from natural gas and petroleum systems and from abandoned oil and natural gas wells were source of approximately 33 percent of U.S. methane emissions and approximately four percent of U.S. greenhouse gas emissions. In the South Coast AQMD region, there have been examples of large leaks such as Aliso Canyon, where 109,000 metric tons of methane emissions were released between October 2015 and February 2016.

For this rulemaking, staff did not conduct lifecycle analyses related to the BARCT assessment for either the electricity or natural gas systems as a lifecycle analysis is not required under California Health and Safety Code Section 40406 for a BARCT assessment. However, other organizations have conducted lifecycle analyses which show overall NOx reductions when moving to zero-emissions. A 2021 Northeast States for Coordinated Air Use Management (NESCAUM) study estimating NOx reductions for residential scenarios where fossil fuel-burning furnaces are replaced with heat pumps found significant reductions in NOx along with sulfur dioxide and carbon dioxide.³⁸ A 2023 NESCAUM study also found emission reductions for different scenarios.³⁹ A 2022 Energy Innovation Policy & Technology study found that switching to heat pumps for industrial processes reduces NOx emissions.⁴⁰

Considerations for Dry Cleaners

Staff has been engaging in discussion with representatives of the dry cleaning industry to discuss challenges PAR 1146.2 may pose to their operations. The dry cleaners' primary concern is the high upfront cost to install a new zero-emission unit. Staff acknowledges some zero-emission technologies have higher upfront costs, but as zero-emission technologies become more mature and more widely adopted in the market, there will be less cost impact. In addition, staff is projecting lifetime utility savings based on future projected natural gas and electricity prices. The cost to operate heat pumps is lower than most electric appliances because they are so energy efficient; over the lifetime of the unit, that initial cost increase could be recovered. In addition, there are federal, state, and local incentive funding specifically to incentivize the switch from combustion to heat pump technologies. South Coast AQMD is also developing a rebate program to help lower the cost for some consumers and small businesses and will be centralizing information for incentive and financing opportunities offered by other agencies and organizations.

³⁹ NESCAUM and OTC, Residential Building Electrification in the Northeast and Mid-Atlantic, <https://otcair.org/upload/Documents/Reports/Residential%20Building%20Electrification%20Final%20Report%20August%202023.pdf>

⁴⁰ Energy Innovation Policy & Technology LLC, <https://energyinnovation.org/wp-content/uploads/2022/10/Decarbonizing-Low-Temperature-Industrial-Heat-In-The-U.S.-Report-2.pdf>

Staff proposed several alternative compliance options, a limited exemption for small businesses, and a longer compliance timeline, further detailed in Chapter 3, that dry cleaners would be able to utilize, including:

- Paragraph (i)(1) provides an alternative compliance option for when utility upgrades delay compliance with zero-emission limits. When the applicable utility company is unable to provide the necessary power which is beyond the owner or operator's reasonable control, the owner or operator can request an extension of up to ~~36~~60 months for compliance.
- Paragraph (i)(4) provides an alternative compliance option for emergency replacement when an owner or operator requires a short-term replacement due to sudden unit failure after the applicable Table 3 compliance date if an electrical upgrade is needed to operate a unit that complies with Table 2 emission limits. In this situation, the owner or operator may elect to install and operate a temporary unit that complies with Table 1 emission limits for up to six months.
- For a dry cleaner in a property under lease, paragraph (i)(6) provides another alternative compliance option that allows an extension of up to 24 months to comply with the Table 2 emission limits, if the installation is delayed beyond the reasonable control of the owner or operator of the unit.
- Paragraph (i)(7) provides an alternative compliance option that allows for an extension of up to 18 months from the applicable compliance date for when installation is delayed because construction is required to expand the space designed to house or relocate the unit, and associated equipment necessary for operating the unit, excluding units utilizing the alternative compliance options specified in paragraphs (i)(1), (i)(2), (i)(5), and (i)(6).
- There is also an exemption in paragraph (k)(5) that the provisions of paragraph (d)(3) regarding replacing existing units once they reach their defined unit age in the rule shall not apply to units installed in facilities that meet the Rule 102 definition of a small business. For small businesses, existing units can be operated until their natural replacement after the applicable Table 3 compliance date.
- Boilers operated by dry cleaners are categorized as high temperature units, for which PAR 1146.2 has proposed a later zero-emission implementation date (i.e., 2033 for existing buildings).

Staff will continue to monitor all the challenges for zero-emission implementation and will conduct a technology check-in and report the findings to the Stationary Source Committee by ~~January 1, 2028~~June 1, 2027, before the compliance dates for the high temperature units go into effect.

Considerations for Low-Use

The existing rule includes a low-use exemption for existing older Type 2 units with annual fuel use of 9,000 therms. Those units were manufactured prior to January 1, 2000, with NO_x emissions higher than 30 ppmv NO_x. PAR 1146.2 proposes to phase out the existing 9,000 therms exemption when zero-emission implementation starts and include a new low-use exemption as a transitional

option. The new low-use exemption from Table 2 zero-emission requirements is for an existing Type 2 unit installed prior to the date of rule adoption that meets Table 1 emission limits (i.e., 20 ppmv NO_x and 400 ppmv CO) with fuel use meeting a low-use threshold for annual fuel use. This low-use threshold is 3,000 therms per year for units with a rated heat input capacity greater than 1 MMBtu/hr, but less than or equal to 2 MMBtu/hr, or 2,000 therms per year for units with a rated heat input capacity greater than 400 kBtu/hr, but less than or equal to 1 MMBtu/hr. For context, annual use of 3,000 therms is about 16 percent of normal fuel use for a 1 MMBtu/hr unit and 2,000 therms is about 27 percent of normal fuel use for a 400 kBtu/hr unit. This low-use provision provides another transitional option for phasing in existing units to the zero-emission requirement.

Hot Water Requirements for Health Facilities and Use in Hospitals

The 2022 California Plumbing Code includes sections on Water Supply and Distribution; Domestic Hot-Water Distribution Systems for Health Facilities and Clinics. For laundry, 160 degrees Fahrenheit hot water is acceptable, or 140 degrees Fahrenheit hot water if the laundry also passes through a tumbler dryer at 180 degrees Fahrenheit. Hot water between 158 to 176 degrees Fahrenheit is used to reprocess cloths and mop heads.⁴¹ For dishwashing equipment, 180 degrees Fahrenheit is acceptable, and 125 to 180 degrees Fahrenheit booster heaters are acceptable as a second piece of equipment for dishwashing. There is a redundancy requirement for dishwashing and minimum patient services such as handwashing and bathing. The California Plumbing Code hot water use temperature requirements for health facilities and clinics are displayed in the following table.

Table 2-7. California Plumbing Code Hot Water Temperature Requirements (Degrees Fahrenheit)

Clinical	Dietary	Laundry	Dishwashing
105-120	120	160	180

Staff visited a hospital in Los Angeles with sixteen natural gas-fired units below 2 MMBtu/hr, spread between two buildings. The units included four for domestic hot water and 12 for space heating, with the highest water temperature output at 180 degrees Fahrenheit. This also included redundant units, and units are often oversized. Hospital steam for sterilization is usually generated by larger boilers permitted under Rule 1146. The hospital is considering replacing conventional domestic hot water Type 1 units with heat pumps. One challenge is that it may take five to seven years for the California Department of Health Care Access and Information project approval to replace a boiler or hot water heater.

Staff also contacted the all-electric University of California, Irvine (UCI) Medical Center, which is anticipated to be operational in 2025 with the Acute Care Center and Central Utility Plant operational in 2024.⁴² Future plans include fuel cells and battery storage. The heat pump COP is three, or 300 percent more efficient than a conventional unit. The team noted lower maintenance costs of \$338,000 for all-electric distributed steam compared to \$1,751,000 for gas-fired, and \$737,000 annual operational cost savings. There was an estimated 3.8-year simple payback. In

⁴¹ CDC, Best Practices for Environmental Cleaning in Healthcare Facilities, <https://www.cdc.gov/hai/pdfs/resource-limited/environmental-cleaning-RLS-H.pdf>

⁴² Building Design+Construction, UC Irvine takes sustainability to new level with all-electric medical center, <https://www.bdcnetwork.com/uc-irvine-takes-sustainability-new-level-all-electric-medical-center>

addition to zero-emission space and water heating, electric appliances were installed in the kitchen. The team working on the UCI project mentioned they obtained approval from the California Department of Health Care Access and Information for the initial phase in about one year. The experience they shared is to have early planning and good communication and to implement the project in phases.

Hot Water Requirements and Use in Restaurants

Requirements for restaurant hot water are included in the California Retail Food Code.^{43, 44, 45} Hot water generation and distribution systems must be sufficient to meet the peak hot water demands throughout the food facility. In sizing the water heater, the peak hourly demands for all sinks, dishwashing machines, etc., are added together to determine the minimum required recovery rate. A minimum of 120 degrees Fahrenheit should be supplied from the faucet and a minimum of 100 degrees Fahrenheit for handwashing.

Restaurant dishwashers use a majority of the hot water and require 180 degrees Fahrenheit. Restaurants can use electric “booster heaters” to achieve the required temperature. Restaurants may also choose to utilize a distributed generation water system to save on water use and cost. A distributed generation water system consists of the primary heat pump water heater serving key points such as kitchen sinks and point-of-use electric heaters serving most others.

Staff visited a facility with a restaurant which utilized 500,000 Btu to 2 MMBtu sized units. Electric booster heaters were used for dishwashing to increase the temperature from 120 to 170 degrees Fahrenheit, as shown in the image below. For restaurant sanitation, 120 degrees Fahrenheit water is used so there was no need for hot water at a temperature above 180 degrees Fahrenheit.

Another potential option for commercial kitchens and other facilities are products which can use heat recovery from air conditioners or chillers to provide hot water. This technology recovers waste heat from refrigeration systems and uses it to heat water. The products include tanks with built-in heat recovery and stand-alone remote units that can connect to any tank. A heat pump could supplement for high demand situations.⁴⁶

Figure 2-5-6. Examples of Dishwashing Unit (Left) and Electric Booster Heater (Right)

School Districts

Heat pump technology can be utilized in many applications for space and water heating, including in schools. Department of Energy Better Buildings® has presented a case study for commercial building heat pump implementation by the Los Angeles Unified School District (LAUSD).⁴⁷ LAUSD utilizes electric heat pump rooftop and wall-hung units, and other heat pump technologies, as the primary option for space heating and cooling systems for its school and administrative facilities. LAUSD has been transitioning to unitary heat pumps for space heating of buildings with a capacity of three to ten tons with plans to expand to larger spaces as larger heat pumps become commercially available. LAUSD started by replacing the smaller gas units ranging from five to ten tons as they reached the end of their life with electric units. LAUSD has replaced sixty-five percent of their decentralized HVAC units with electric heat pumps, with plans to achieve one hundred percent by 2040. Since the beginning of the project, LAUSD has saved around \$139,000 per month on utility costs. The lifecycle costs of each heat pump are projected to be twelve percent lower than the lifecycle cost of the gas heating units at current utility rates. They have also utilized on-site solar PV systems to offset the increase in electricity operating costs from the electric unitary heat pumps. As utility rates and initial costs have shifted, capital and operating costs are now lower for the electric units. Moving forward, when the options for high-capacity heat pumps become available, they will create a comprehensive plan to update electrical capacity to accommodate heat pump RTUs for larger spaces. In addition, LAUSD has started heat pump training for their engineering and maintenance staff to ensure any issues can be addressed quickly.

⁴⁷ U.S. DOE Better Buildings Case Study, https://betterbuildingssolutioncenter.energy.gov/sites/default/files/attachments/LAUSD%20Heat%20Pump%20Rooftop%20Units_.pdf

They have equipped all of their electric units with advanced controls that allow for centralized monitoring to facilitate maintenance and ensure efficient operations.

Incentives

There are several federal and state incentives for zero-emission commercial appliances. Section 179D of the Internal Revenue Code allows deductions for energy-efficient commercial buildings, including new or existing buildings.⁴⁸ The Inflation Reduction Act extended and expanded these tax deductions.⁴⁹ TECH Clean California launched more state-wide incentives for multifamily and commercial water heating in 2023.⁵⁰ Other state programs can provide more incentives such as for new construction of all-electric multifamily pool heating.⁵¹ There are also utility incentives for appliances in commercial buildings, including SCE's Willdan Commercial Energy Efficiency Program, which incentivizes replacement of an existing electric resistance or gas-fired water heater with a packaged heat pump water heater.⁵² San Diego Gas and Electric's Comprehensive Energy Management Solutions Program provides heat pump water heater rebates.⁵³

CHAPTER 3: SUMMARY OF PROPOSALS

INTRODUCTION

PROPOSED AMENDED RULE STRUCTURE

PROPOSED AMENDED RULE 1146.2

INTRODUCTION

The main objective of PAR 1146.2 is to propose NO_x limits that represent BARCT for the applicable equipment. PAR 1146.2 also deletes outdated rule language and reorganizes the rule structure to be consistent with recently amended or adopted rules. The proposed revised rule structure and key provisions are discussed below.

PROPOSED AMENDED RULE STRUCTURE

- (a) *Purpose*
- (b) *Applicability*
- (c) *Definitions*
- (d) *Requirements*
- (e) *Unit Age*
- (f) *Certification*
- (g) *Demonstrations of Compliance with Emission Limits*
- (h) *Identification of Compliant Units*
- (i) *Alternative Compliance Options*
- (j) *Labeling, Reporting, and Recordkeeping Requirements*
- (k) *Exemptions*

PROPOSED AMENDED RULE 1146.2

The proposed amended rule separates the purpose and applicability to be consistent with recently adopted and amended rules.

The table below shows the emission limits for new units in the current Rule 1146.2 and proposed revisions in PAR 1146.2.

Table 3-1. Summary of Emission Limits for New Units in Rule 1146.2 and New Revisions in PAR 1146.2

Rule 1146.2 Current Section	Unit Type	Compliance Date	Emission Limit (ppmv at 3%O ₂ , dry)	PAR 1146.2 Revision*
Rule 1146.2 (c)(1)	Type 2	2000	30 ppmv NO _x ; 400 ppmv CO	Obsolete; section removed
Rule 1146.2 (c)(2)	Type 1	2001	40 ng/J NO _x (55 ppmv NO _x)	Obsolete (except for pool heaters); section removed
Rule 1146.2 (c)(2)	Type 1 Pool Heaters	2001	40 ng/J NO _x (55 ppmv NO _x)	Current limits; now included in PAR 1146.2 (d)(1) and Table 1
Rule 1146.2 (c)(7)	Type 2	2010	14 ng/J NO _x (20 ppmv NO _x)	
Rule 1146.2 (c)(8)	Type 1 (excluding Pool Heaters)	2012	14 ng/J NO _x (20 ppmv NO _x)	

* PAR 1146.2 zero-emission requirements for new units installed in new and existing buildings are included in PAR 1146.2 (d)(2).

The table below shows the phase-out/retrofit requirements in the current rule and proposed revisions in PAR 1146.2. Phase-out/retrofit was required in Rule 1146.2 for unregulated old units to phase into the emission limits.

Table 3-2. Summary of Phase-out/Retrofit Requirements in Rule 1146.2 and New Revisions in PAR 1146.2

Rule 1146.2 Current Section	Unit Type and Age	Compliance Date	Emission Limit (ppmv at 3%O ₂ , dry)	PAR 1146.2 Revision*
Rule 1146.2 (c)(3)-(c)(5)	Type 2; Manufactured prior to 2000	2002-2006	30 ppmv NO _x	Should have met the limits; now included in PAR 1146.2 (d)(6) as a compliance tool if a non-compliant unit is found
Rule 1146.2 (c)(11)	Type 2; Manufactured and purchased prior to 2000 and sold/installed by December 31, 2010	Until Dec 31, 2010	20 ppmv NO _x	Obsolete; section removed

* Additionally, PAR 1146.2 will require units reaching their unit age after PAR 1146.2 Table 3 zero-emission compliance dates of their applicable categories to phase into zero-emission requirement as specified in PAR 1146.2 (d)(3).

PAR 1146.2 Purpose [Subdivision(a)]

The purpose of this rule is to reduce NO_x emissions from water heaters, boilers, and process heaters as defined in this rule.

PAR 1146.2 Applicability [Subdivision(b)]

The provisions of this rule are applicable to manufacturers, distributors, retailers, resellers, installers, owners, and operators of units that have a rated heat input capacity less than or equal to 2 MMBtu/hr. Those units could be sold through physical stores or online. An installer installing a noncompliant unit purchased online is in violation of the rule.

The provisions of the rule are primarily enforced through the supply chain (manufacturers, distributors, installers, etc.); however, enforcement staff also enforces the rule at commercial and industrial facilities that own and operate Rule 1146.2 units, especially if those facilities also own and operate other units that require a South Coast AQMD permit to operate.

Refurbishers were also subject to Rule 1146.2 but have been removed from PAR 1146.2 applicability to avoid redundancy. The term reseller has been added to PAR 1146.2 applicability. A refurbisher can be a manufacturer, reseller, or installer; therefore, removing the term refurbisher and adding the term reseller does not change the applicability.

PAR 1146.2 Definitions [Subdivision(c)]

The following are key new definitions for Proposed Amended Rule 1146.2. For all definitions, refer to PAR 1146.2 released with the staff report.

COMPLIANCE PORTAL in paragraph (c)(3), which means:

“the dedicated webpage on the South Coast AQMD website for submitting reports, notifications, or any documents to comply with South Coast AQMD rule(s)”

EXISTING BUILDING in paragraph (c)(4), which means:

“a building that is not a New Building as defined in this rule. Existing Building includes any structures on the property including, but not limited to, sheds, detached garages, pools, and spas”

HIGH TEMPERATURE UNIT in paragraph (c)(8), which means:

“any Unit that is designed and used to produce steam or to heat water above 180 degrees Fahrenheit”

INSTALL in paragraph (c)(10), which means:

“the action of an Installer to place a Unit in a position ready for use”

INSTALLER in paragraph (c)(11), which means:

“a person who Installs a Unit and is required to obtain a license issued by the Department of Consumer Affairs Contractors State License Board for a classification related to buildings and appliances”

Potential license requirements for installers include Department of Consumer Affairs Contractors State License Board Licensing Classifications C-4 - Boiler, Hot Water Heating and Steam Fitting Contractor; C-53 – Swimming Pool Contractor; and other license classifications.

MOBILE HOME in paragraph (c)(13), which means:

“a prefabricated structure on a permanently attached chassis”

NEW BUILDING in paragraph (c)(14), which means:

“a building that is newly constructed or a building with a major alteration which changes the occupancy classification of a building, which means a change in the formal designation of the primary purpose of the building pursuant to 2022 Title 24 California Building Code Part 2 Chapter 3 for occupancy classification and use, and that does not have a Unit installed prior to the applicable Table 3 compliance dates. New Building comprises any structures on the property including, but not limited to sheds, detached garages, pools, and spas”

SMALL BUSINESS in paragraph (c)(25), which is:

“as defined by Rule 102”

At the time of rule adoption, the definition of a Small Business in Rule 102 states, “a business which is independently owned and operated and meets the following criteria, or if affiliated with another concern, the combined activities of both concerns shall meet these criteria: (A) the number

of employees is 10 or less; and (B) the total gross annual receipts are \$500,000 or less; or (C) not-for-profit training center.”

STANDARD CONDITIONS in paragraph (c)(26), which is:

“as defined by Rule 102”

At the time of rule adoption, the definition of Standard Conditions in Rule 102 states, “gas temperature of 60°F and a gas pressure of 760 mm Hg (14.7 pounds per square inch) absolute.”

PAR 1146.2 Requirements [Subdivision(d)]

Paragraph (d)(1) – Current Rule 1146.2 Emission Limit

The provisions that were originally included in paragraphs (c)(2), (c)(7), and (c)(8) in Rule 1146.2 have been moved to paragraph (d)(1) in PAR 1146.2 to display current emission limits. Paragraph (d)(1) provides that no person shall manufacture, supply, sell, offer for sale, or install, for use within the South Coast AQMD, any unit subject to this rule, unless the unit is certified pursuant to subdivision (f) not to exceed the applicable NO_x and CO emission limits specified in PAR 1146.2 Table 1, prior to the compliance dates specified in PAR 1146.2 Table 3.

Table 3-3. PAR 1146.2 Table 1 (NO_x and CO Emission Limits)

Equipment Category	NO_x Emission Limit*	CO Emission Limit*
Type 1 Units, excluding Pool Heaters	14 ng/J or 20 ppmv	N/A**
Type 1 Pool Heaters	40 ng/J or 55 ppmv	N/A**
Type 2 Units	14 ng/J or 20 ppmv	400 ppmv

* Ng/J of NO_x (calculated as NO₂) of heat output or the specified ppmv of NO_x or CO at three percent oxygen (O₂) correction, on a dry basis.

** Type 1 units are not subject to a CO limit by Rule 1146.2 but may be subject to CO limits by other South Coast AQMD rules.

Paragraph (d)(2) – PAR 1146.2 BARCT Emission Limit for New Installations

PAR 1146.2 establishes updated BARCT NO_x and CO emission limits for applicable equipment as shown in Table 2. This paragraph provides that no person shall manufacture, supply, sell, offer for sale, or install, for use in the South Coast AQMD, any unit subject to this rule, unless such unit complies with the applicable Table 2 emission limits by Table 3 compliance dates.

Since the rule regulates units fired with, or designed to be fired with, natural gas, the emission limits only apply to the natural gas-fired mode for a dual fuel system. On and after the applicable compliance dates in PAR 1146.2 Table 3, any dual-fuel unit capable of being fired on natural gas and another gas, at the end of its unit age, would not be allowed to operate in natural gas-fired mode if that mode does not meet the zero-emission limit. In this case, the owner or operator could restrict the unit from operating in such a mode.

**Table 3-4. PAR 1146.2 Table 2
(Zero-Emission Limits, Compliance Schedule, and Unit Age)**

Equipment Category	NO _x and CO		Unit Age (years)
	Emission Limits (ppmv)	Compliance Schedule	
Type 1 Unit*	0	Phase I	15
Instantaneous Water Heater ≤ 200,000 Btu/hr	0		25
Instantaneous Water Heater > 200,000 Btu/hr	0	Phase II	25
Type 1 Pool Heater	0		15
Type 2 Unit**	0		25
Type 1 High Temperature Unit	0	Phase III	25
Type 2 High Temperature Unit	0		25

* Referring to a Type 1 Unit that is not a High Temperature Unit, Type 1 Pool Heater, or Instantaneous Water Heater.

** Referring to a Type 2 Unit that is not a High Temperature Unit or Instantaneous Water Heater.

**Table 3-5. PAR 1146.2 Table 3
(Compliance Dates for Zero-Emission Limits)**

Phase	Building Type	Compliance Date
Phase I	New Buildings	January 1, 2026
	Existing Buildings	January 1, 2029
Phase II	New Buildings	January 1, 2028
	Existing Buildings	January 1, 2031
Phase III	New Buildings	January 1, 2029
	Existing Buildings	January 1, 2033

Paragraph (d)(3) – Zero-Emission for Existing Units after Their Unit Age

PAR 1146.2 requires units reaching their unit age after the Table 3 compliance dates of their applicable categories to phase into the zero-emission requirement. On and after the Table 3 compliance dates, an owner or operator of a unit shall not operate a unit which exceeds Table 2 emission limits once the unit age determined pursuant to subdivision (e) is greater than or equal to the applicable Table 2 unit age. All units installed prior to the applicable Table 3 compliance dates will be subject to this requirement, including older Type 1 units installed prior to 2010 and all existing units in RECLAIM and former RECLAIM facilities. Units installed or used for residential structures or facilities meeting the Rule 102- Definitions (Rule 102) definition of a small business are exempted from this requirement pursuant to paragraph (k)(4) or (k)(5), those units will have to meet the Table 2 emission limits upon natural replacement.

For example, if an existing Type 1 unit is not used in a residential structure or small business facility, it is subject to the paragraph (d)(3) requirement. If this unit is 18 years old (i.e., beyond its unit age as indicated in PAR 1146.2 Table 2) by January 1, 2029, the Phase II zero-emission compliance date, it must comply with the zero-emission requirement no later than January 1, 2029.

Another example is also for an existing Type 1 unit subject to the paragraph (d)(3) requirement that is not used in a residential structure or small business facility. If this unit is 12 years old (i.e., before end of unit age as indicated in PAR 1146.2 Table 2) on January 1, 2029, the Phase II zero-emission compliance date, it is not subject to the zero-emission requirement until 2032 at its unit age.

Paragraph (d)(4) – Emission Demonstration at Unit Modification

Paragraph (d)(4) of PAR 1146.2 provides guidance for an owner or operator to demonstrate that a modified unit meets the NO_x and CO emission limits in subdivision (d).

Paragraph (d)(5) – Emission Limits at Burner Modification or Replacement

Paragraph (d)(5) specifies the applicable emission limit when an owner or operator modifies or replaces a burner for any unit. If the modification or replacement occurs prior to the applicable compliance dates in Table 3 or before the unit reaches its unit age, the emission limit in Table 1 will apply. If the modification or replacement occurs on and after the applicable compliance dates in Table 3 and when the unit has reached its unit age in Table 2, the emission limit in Table 2 will apply. This provision addresses stranded assets by allowing a unit that has not reached the end of its unit age but requires a burner replacement after the Table 2 limits have gone into effect, to be retrofit to continue operation. Once the unit reaches the end of its unit age, it will have to meet the Table 2 emission limits.

Paragraph (d)(6) – Type 2 Unit Manufactured Prior to January 1, 2000

The provisions that were originally included in paragraphs (c)(3), (c)(4), and (c)(5) in Rule 1146.2 have been converted into paragraph (d)(6) in PAR 1146.2. These units should already comply with the emission limits, and this provision is included in PAR 1146.2 (d)(6) as a compliance tool if a non-compliant unit is found. Paragraph (d)(6) provides that except for units at a RECLAIM or former RECLAIM facility, an owner or operator shall not operate any Type 2 unit manufactured prior to January 1, 2000, in the South Coast AQMD which does not meet the emission limit of 30 ppmv (corrected at ~~3~~three percent O₂ correction, on a dry basis) or 0.037 pound NO_x per million Btu of heat input and no more than 400 ppmv of carbon monoxide (at ~~3~~three percent O₂, dry).

Paragraph (d)(7) – If Failing to Meet the Exemption Criteria

An owner or operator of a unit that elects to comply with the exemptions in paragraph (k)(2), (k)(3), or (k)(5) will lose the exemption and be subject to the applicable emission limits within 180 days if they fail to demonstrate meeting the criteria for the exemption. The owner or operator of the unit shall not operate the unit that exceeds the applicable Table 1 emission limits within 180 days of failing to demonstrate compliance with paragraph (k)(2) pursuant to paragraph (g)(2); shall not operate the unit that exceeds the applicable Table 2 emission limits within 180 days of failing to demonstrate compliance with paragraph (k)(3) pursuant to paragraph (g)(2); or shall not operate the unit that does not comply with paragraph (d)(3) within 180 days of failing to meet the Rule 102 definition of a small business. Paragraph (d)(7) sets a backstop if the exemption criteria cannot be demonstrated and requires a timeline of up to 180 days for the compliance of applicable emission limits.

PAR 1146.2 Unit Age [Subdivision(e)]

Subdivision (e) provides guidance for an owner or operator of a unit to determine unit age.

Paragraph (e)(1) – Unit Age Determination

Paragraph (e)(1) provides guidance for an owner or operator of a unit to determine unit age. Unit age shall be based on the original date of manufacture determined by an invoice from purchase of unit provided by the manufacturer; the original unit manufacturer's identification or rating plate permanently affixed to the unit; or any other method of determining unit age that can be substantiated through written information as approved by the Executive Officer. The unit shall be deemed at the end of its unit age as of January 1, 2025, for any unit where the unit age cannot be determined pursuant to subparagraph (e)(1)(A).

PAR 1146.2 Certification [Subdivision(f)]

Subdivision (f) provides guidance to manufacturers regarding unit certification. Subdivision (f) in PAR 1146.2 was originally subdivision (d) in Rule 1146.2.

Paragraph (f)(1) – Independent Testing Laboratory

The manufacturer shall obtain confirmation from an independent testing laboratory prior to applying for certification for a natural gas unit that each unit model or retrofit kit complies with the applicable requirements of subdivision (d). This confirmation shall be based upon emission source tests of a randomly selected unit of each model, and the protocol shall be adhered to during the confirmation testing of all units subject to this rule.

Paragraph (f)(2) – Applying for Unit Certification

When applying for unit(s) certification, the manufacturer shall submit to the Executive Officer the following: a statement that the model is in compliance with subdivision (d), signed and dated, attesting to the accuracy of all statements; general information including name and address of manufacturer, brand name, and model number as it appears on the unit rating plate; a description of each unit being certified; and a source test report verifying compliance with the emission limits in subdivision (d) for each model to be certified. The source test report shall be prepared by the confirming independent testing laboratory and shall contain all the elements identified in the protocol for each unit tested.

Paragraph (f)(3) – Timeline

When applying for unit certification, the manufacturer shall submit the items identified in paragraph (f)(2) no more than 180 days after the date of the source test identified in subparagraph (f)(2)(D).

Paragraph (f)(4) – Unit Certification

The Executive Officer shall certify a unit model which complies with the provisions of subdivision (d) and of paragraphs (f)(1), (f)(2), and (f)(3).

PAR 1146.2 Demonstrations of Compliance with Emission Limits [Subdivision(g)]*Paragraph (g)(1) – Source Test Report*

The owner or operator that elects to demonstrate compliance pursuant to subparagraph (d)(4)(B) shall maintain a copy of the South Coast AQMD approved source test report or make it available to the Executive Officer upon request. The source test report shall, at a minimum, include: the emissions limit of the unit in ppmv or ng/J of NO_x or ppmv of CO of heat output; the South Coast AQMD approved test method and Independent Testing Laboratory for the source test; the model and serial numbers of the unit(s); and the rated heat input capacity of the unit(s).

Paragraph (g)(2) – Demonstrate Compliance for Exemption in Paragraph (k)(2) or (k)(3)

The owner or operator of a unit that elects to comply with the exemption in paragraph (k)(2) or (k)(3), shall demonstrate compliance with the annual therm limit determined using one of the following methods: fuel usage recorded by a non-resettable totalizing fuel meter, corrected to standard conditions; fuel usage calculated by multiplying the number of hours recorded by a non-resettable totalizing time meter and the rated heat input capacity of the unit, as calculated using Equation 1 in the rule; or monthly fuel billing statement or equivalent documentation, which can include an e-statement or a download from the utility website. The fuel meter or time meter is required to be non-resettable and calibrated according to the manufacturer's recommendation. The owner or operator also shall maintain the fuel usage records for a period of not less than three years as specified in subparagraph (j)(4)(D).

PAR 1146.2 Identification of Compliant Units [Subdivision(h)]

Subdivision (h) outlines the procedure and requirements for identification and verification of compliant units. Subdivision (h) in PAR 1146.2 was originally subdivision (f) in Rule 1146.2.

Paragraph (h)(1) – Newly Manufactured Units

The manufacturer shall display the model number of the unit complying with subdivision (d) on the shipping carton and permanent rating plate. The manufacturer shall also display the certification status on the shipping carton and on the unit.

Paragraph (h)(2) – Certified Retrofit Kits

The manufacturer shall display the model number of the retrofit kit and manufacturer and model of applicable units on the shipping carton and in a plainly visible portion of the retrofit kit.

PAR 1146.2 Alternative Compliance Options [Subdivision(i)]

Subdivision (i) provides alternative compliance options for different considerations, including utility upgrade, multiple units, emergency replacement, mobile homes, property under lease, and construction upgrade.

Paragraph (i)(1) – Alternative Compliance Option for Utility Upgrades

Paragraph (i)(1) provides an alternative compliance option when an owner or operator of a unit required to meet the Table 2 emission limits will encounter delays beyond their reasonable control and cannot meet the applicable Table 3 compliance date, or paragraph (d)(3) requirement, because a utility upgrade is required to provide the necessary power to operate the unit.

The owner or operator shall notify the Executive Officer through the compliance portal and request an extension pursuant to subparagraph (i)(1)(A) and obtain a letter from the Executive officer pursuant to subparagraph (i)(1)(B). The owner or operator shall notify the Executive Officer at least 90 days prior to the unit's applicable compliance date in Table 3 or paragraph (d)(3) to request an extension of no more than ~~18~~24 months from the applicable compliance date and obtain a letter from the Executive Officer prior to the unit's compliance date approving or disapproving the extension. If the need for the utility upgrade is discovered when a unit is being replaced due to sudden unit failure, the owner or operator of the unit shall notify the Executive Officer through the compliance portal 30 days after the date the unit became non-operational to request an extension of no longer than ~~18~~24 months from the date of unit failure. In this case, the owner or operator shall obtain a letter from the Executive Officer through the compliance portal within 90 days of the notification.

Furthermore, if the utility upgrades will not be completed within the initial ~~18~~24-month extension approved pursuant to subparagraph (i)(1)(A), the owner or operator may request an additional extension of no more than ~~18~~24 months through the compliance portal at least 90 days prior to the end of the initial ~~18~~24-month extension; and obtain a letter from the Executive Officer through the Compliance Portal prior to the end of the initial extension. If the utility upgrades will not be completed within the additional 24-month extension approved pursuant to subparagraph (i)(1)(C), the owner or operator may request a further extension of no more than 12 months through the Compliance Portal at least 90 days prior to the end of the additional 24-month extension and obtain a letter from the Executive Officer through the Compliance Portal prior to the end of the additional 24-month extension.

The owner or operator shall provide a progress report to the Executive Officer through the Compliance Portal every six months after the start of the initial extension approved pursuant to subparagraph (i)(1)(B) and for the applicable extension period(s) approved pursuant to subparagraphs (i)(1)(C) and (i)(1)(D), which includes, but is not limited to, the status of the utility upgrade, the estimated date the utility provider will complete the utility upgrade, and documentation which justifies the update to estimated date for completion.

The owner or operator also shall provide a follow-up notification to the Executive Officer through the Compliance Portal no later than 72 hours after the unit complying with the Table 2 emission limits has been installed; and maintain records pursuant to paragraph (j)(6). If a unit is not operational during the extension(s) approved pursuant to subparagraphs (i)(1)(B), (i)(1)(C), and (i)(1)(D) ~~or clause (i)(1)(C)(ii)~~, the owner or operator may elect to operate a temporary unit during the extension, provided the temporary unit complies with Table 1 emission limits; no later than 72 hours after the date the temporary unit was installed, notify the Executive Officer through the

compliance portal; and no later than 72 hours after the date the temporary unit was disconnected, notify the Executive Officer through the compliance portal.

Paragraph (i)(2) – Alternative Compliance Option for Multiple Units

Paragraph (i)(2) provides an alternative compliance option for when an owner or operator has five or more units across facilities that are required to meet the Table 2 emission limits within two consecutive calendar years pursuant to paragraph (d)(3). That means within a period of two consecutive calendar years, those units are reaching their unit age and should be replaced with zero-emission units. The owner or operator may submit an alternative compliance plan requesting alternative compliance date(s) by submitting the alternative compliance plan at least one year prior to the earliest compliance date, with a filing fee payment pursuant to Rule 306 – Plan Fees ([Rule 306](#)); and specifying compliance date(s) in the alternative compliance plan for the number of units to meet the Table 2 emission limits as three or at least 30 percent of the units by the latest applicable compliance date, at least 30 percent of the units one year after the latest applicable compliance date, and the remaining units two years after the latest applicable compliance date.

~~Additionally, In lieu of subparagraph (i)(2)(B), if a unit meets the requirements to apply for the alternative compliance option for utility upgrades pursuant to paragraph (i)(1), the~~ owner or operator ~~of five or more units electing to comply by submitting an alternative compliance plan in subparagraph (i)(2)(A) will encounter delays beyond the reasonable control of the owner or operator to meet the applicable compliance dates because a utility upgrade is required and the applicable utility company is unable to provide the necessary power to operate the Units, as demonstrated with documents specified in paragraph (j)(6), the owner or operator of the Units may~~ elect to include a request in their alternative compliance plan for an extension. Initially, the extension is no longer than ~~18~~24 months from the earliest compliance due date of the units ~~included~~ in the alternative compliance plan ~~submitted pursuant to subparagraph (i)(2)(A), by including the documentation listed in paragraph (j)(6) with the application for an alternative compliance plan, and specifying alternative compliance date(s) in the alternative compliance plan for the number of units to meet the Table 2 emission limits as pursuant to clause (i)(2)(C)(i). The alternative compliance schedule for units that require utility upgrades pursuant to clauses (i)(2)(C)(i), (i)(2)(C)(ii), and (i)(2)(C)(iii) differs from the alternative compliance schedule in subparagraph (i)(2)(B). If utility upgrades are required, the alternative schedule requires 50 percent of the units to be upgraded within two years of the end of the approved extension period, with the remaining 50 percent the following year. The compliance schedule is a little shorter as facilities have time upfront, while the utilities are being upgraded, to plan, design, and purchase zero-emission equipment. If the utility upgrades will not be completed within the initial 1824-month extension in the approved alternative compliance plan period provided in clause (i)(2)(C)(i), the owner or operator may request a second extension of no more than 24 months by submitting a revised alternative compliance plan at least 180 days prior to the end of the initialfirst 1824-month extension to request an additional extension of no more than 1824 months before initiating the alternative compliance schedule specified in subparagraph (i)(2)(B), with a filing fee payment pursuant to Rule 306—Plan Fees, and specifying revised alternative compliance date(s) in the alternative compliance plan for the number of units to meet the Table 2 emission limits as pursuant to clause (i)(2)(C)(ii). If the utility upgrades will not be completed within the second 24-month extension period provided in clause (i)(2)(C)(ii), the owner or operator may request a third extension of no more than 12 months by submitting a revised alternative compliance plan at least 180 days prior to the end of the second 24-month extension, with a filing fee payment pursuant to~~

Rule 306; and specifying alternative compliance date(s) in the alternative compliance plan for the number of units to meet the Table 2 emission limits. The owner or operator must obtain written approval from the Executive Officer, as specified in paragraph (i)(3), prior to the earliest compliance due date of all units included in the alternative compliance plan, and if an additional extension(s) was requested pursuant to clauses (i)(2)(C)(ii) and/or (i)(2)(C)(iii), prior to the end of the ~~initial previously~~ approved ~~18-month~~ extension, ~~for any unit included in the alternative compliance plan.~~

For example, six units across several facilities have compliance dates between 2030 and 2032 with two units due for compliance each year, as shown in the table below. In this example, the owner or operator may write and submit an alternative compliance plan pursuant to subparagraph (i)(2)(A). If no utility upgrade is required, the owner or operator may submit an alternative compliance plan pursuant to subparagraph (i)(2)(B). In this example, two units would have a compliance date of 2032, two units would have a compliance date of 2033, and the remaining two would have a compliance date of 2034 in the alternative compliance plan.

Table 3-6. Example for Paragraph (i)(2)(C) with No Required Utility Upgrade

<u>Unit</u>	<u>Compliance Date</u>	<u>Alternative Compliance Date</u>
<u>1</u>	<u>January 1, 2030</u>	<u>January 1, 2032</u>
<u>2</u>	<u>March 1, 2030</u>	
<u>3</u>	<u>February 1, 2031</u>	<u>January 1, 2033</u>
<u>4</u>	<u>April 1, 2031</u>	
<u>5</u>	<u>August 1, 2031</u>	<u>January 1, 2034</u>
<u>6</u>	<u>January 1, 2032</u>	

For this same example, if utility upgrades are required, subparagraph (i)(2)(C) provides the option to request a 24-month extension and submit an alternative compliance plan following clause (i)(2)(C)(i). In this example, three units would have a compliance date in 2034 and the remaining three units would be due in 2035. If the utility upgrades are not complete, the owner or operator may request a second 24-month extension immediately following the first extension. Following clause (i)(2)(C)(ii), three units would be due in 2036 and three units would be due in 2037. If the utility upgrades are still not complete, the owner or operator may request a third 12-month

extension immediately following the second extension. Following clause (i)(2)(C)(iii), three units would be due in 2037 and three units would be due in 2038.

Table 3-7. Example for Paragraph (i)(2)(C) with Utility Upgrade

<u>Unit</u>	<u>Compliance Date</u>	<u>First 24-Month Extension</u>	<u>Alternative Compliance Date</u>	<u>Second 24-Month Extension</u>	<u>Alternative Compliance Date</u>	<u>Third 24-Month Extension</u>	<u>Alternative Compliance Date</u>
<u>1</u>	<u>January 1, 2030</u>	<u>January 1, 2032</u>	<u>January 1, 2034</u>	<u>January 1, 2034</u>	<u>January 1, 2036</u>	<u>January 1, 2035</u>	<u>January 1, 2037</u>
<u>2</u>	<u>March 1, 2030</u>						
<u>3</u>	<u>February 1, 2031</u>						
<u>4</u>	<u>April 1, 2031</u>		<u>January 1, 2035</u>	<u>January 1, 2037</u>	<u>January 1, 2037</u>	<u>January 1, 2038</u>	<u>January 1, 2038</u>
<u>5</u>	<u>August 1, 2031</u>						
<u>6</u>	<u>January 1, 2032</u>						

The owner or operator shall provide a progress report to the Executive Officer through the Compliance Portal every six months after the start of the initial extension approved pursuant to clause (i)(2)(C)(i) for the applicable extension period(s) approved pursuant to clauses (i)(2)(C)(ii) and (i)(2)(C)(iii), which includes, but is not limited to, the status of the utility upgrade, the estimated date the utility provider will complete the utility upgrade, and documentation which justifies the update to estimated date for completion.

The owner or operator shall obtain written approval from the Executive Officer, as specified in paragraph (i)(3), prior to the earliest compliance due date of all units included in the alternative compliance plan; and obtain written approval if an additional extension(s) was requested pursuant to clauses (i)(2)(C)(ii) and/or (i)(2)(C)(iii) prior to the end of the previously approved extension.

Paragraph (i)(3) – Approval of Alternative Compliance Option for Multiple Units

Paragraph (i)(3) provides language on the approval of the alternative compliance option for multiple units in paragraph (i)(2). The Executive Officer shall review the request for alternative compliance date submitted pursuant to paragraph (i)(2) and provide written approval or disapproval based on whether the following criteria are met: the owner or operator demonstrated they are operating five or more units that are required to be replaced based on unit age pursuant to paragraph (d)(3) to meet Table 2 emission limits within two calendar years; the request was submitted at least one year prior to the earliest applicable compliance date; and the proposed alternative compliance date meets the criteria specified in subparagraph (i)(2)(B) ~~or~~ and subparagraph (i)(2)(C), if applicable.

Paragraph (i)(4) – Alternative Compliance Option for Emergency Replacements

Paragraph (i)(4) provides an alternative compliance option for emergency replacement when an electrical upgrade for more power supply capacity is required to comply with zero-emission limits. An owner or operator of a unit that requires a short-term replacement due to sudden unit failure after the applicable Table 3 compliance date and an electrical upgrade to increase the power supply capacity to operate a unit that complies with Table 2 emission limits, excluding units utilizing alternative compliance options specified in paragraphs (i)(1), (i)(6), and (i)(7) may elect to, for units used in buildings that are not residential structures: install and operate a temporary unit that complies with Table 1 emission limits for up to six months prior to installing a unit that complies with Table 2 emission limits; no later than 72 hours after the date the temporary unit was installed, report the date the existing unit failed and the date the temporary unit was installed through the compliance portal; and no later than 72 hours after the date the temporary unit was disconnected, report the date the temporary unit was disconnected through the compliance portal; and report the date the unit complying with Table 2 emission limits was installed through the Compliance Portal no later than 72 hours after the date the new unit was installed. For units sold for use in residential structures, a unit that complies with Table 1 emission limits can be offered for rent for up to six months prior to installing a unit that complies with Table 2 emission limits.

Paragraph (i)(5) – Alternative Compliance Option for Mobile Homes

Paragraph (i)(5) provides an alternative compliance option with more time to comply with zero-emission limits for mobile homes with an existing instantaneous water heater. An owner or operator of an instantaneous water heater manufactured prior to the date of rule adoption that is installed in a mobile home may elect to install an instantaneous water heater with rated heat input capacity of less than or equal to 200,000 Btu/hr that complies with the Table 1 emission limits ~~until~~[before](#) January 1, 2033, in lieu of the applicable compliance date in Table 3 or paragraph (d)(3). On and after January 1, 2033, any instantaneous water heater with rated heat input capacity of less than or equal to 200,000 Btu/hr manufactured, supplied, sold, offered for sale, or installed for use in a mobile home must meet the Table 2 emission limits upon replacement.

Paragraph (i)(6) – Alternative Compliance Option for Units at a Property Under Lease

Paragraph (i)(6) provides an alternative compliance option for an owner or operator of a unit, when the unit is in a property under lease. The owner or operator of the unit shall be provided an extension of no more than 24 months [from the applicable compliance date](#) to comply with the Table 2 emission limits, if the installation is delayed beyond the reasonable control of the owner or operator of the unit, [excluding units utilizing the alternative compliance options specified in paragraphs \(i\)\(1\), \(i\)\(2\), and \(i\)\(7\)](#), provided the owner or operator: occupies the property under a lease as a tenant before and after the applicable compliance date in Table 3 or paragraph (d)(3); reports the date the existing unit is required to comply no later than 90 days prior to the applicable compliance date in Table 3 or paragraph (d)(3) through the compliance portal; and reports the date the new unit was installed to comply with the Table 2 emission limits through the compliance portal no later than 72 hours after the date the new unit was installed. The intent of this provision is for commercial facilities, such as dry cleaners who typically rent their space, and need additional time to transition to zero-emissions units while the property owner provides utility upgrades. The

landlord of residential rentals has a legal obligation to provide safe and habitable living conditions for the tenants, including providing clean water and functioning heating systems. The provision is not designed for residential rentals, as most renters are not responsible for purchasing large appliances such as water heaters; however, residents are not precluded from utilizing the provision. If a unit is non-operational during the extension specified in paragraph (i)(6), the owner or operator may elect to operate a temporary unit during the extension, provided the temporary unit complies with Table 1 emission limits, and the owner or operator notifies the Executive Officer through the compliance portal no later than 72 hours after the date the temporary unit was installed and no later than 72 hours after the date the temporary unit was disconnected.

Paragraph (i)(7) – Alternative Compliance Option for Construction

Paragraph (i)(7) provides an alternative compliance option for an extension of no more than ~~six~~18 months [from the applicable compliance date](#) to comply with the Table 2 emission limits if the installation is delayed because construction is required to expand the space designed to house [or relocate](#) the Unit, and associated equipment necessary for operating the Unit, excluding Units utilizing the alternative compliance options specified in paragraphs (i)(1), (i)(2), (i)(5), and (i)(6).

The owner or operator electing to utilize this provision shall: report the existing unit is required to be replaced to comply with the Table 2 emission limits through the compliance portal no later than 90 days prior to the applicable compliance date in Table 3 or paragraph (d)(3); report the date the new unit was installed to comply with the Table 2 emission limits through the compliance portal; and maintain records pursuant to paragraph (j)(8). If a unit is non-operational during the extension provided by this provision, the owner or operation may install and operate a temporary unit that complies with Table 1 emission limits during the extension prior to installing a unit that complies with Table 2 emission limits; no later than 72 hours after the date the temporary unit was installed, notify the Executive Officer [through the compliance portal](#); and no later than 72 hours after the date the temporary unit was disconnected, notify the Executive Officer [through the compliance portal](#).

Paragraph (i)(8) – If failing to comply with the alternative compliance option requirements

Paragraph (i)(8) provides clarification regarding compliance when the owner or operator of a unit elects to use any of the alternative compliance options in subdivision (i) but fails to comply with the specified requirements. When that occurs, the owner or operator can no longer use the alternative compliance option and must meet the zero-emission requirements according to paragraph (d)(2), (d)(3), [or subparagraph \(d\)\(5\)\(B\)](#), whichever applicable.

PAR 1146.2 Labeling, Reporting, and Recordkeeping Requirements [\[Subdivision\(j\)\]](#)

Subdivision (j) addresses labeling, reporting, and recordkeeping requirements.

Labeling requirements are common for area source rules. For example, Rule 1111 has several labeling requirements. Labeling requirements are important tools for enforcement, especially when some units distributed to the market can only be installed under certain conditions. While manufacturers ship units into many markets, to ensure the labels are only included on units sold into or within the South Coast AQMD, they may elect to send a sticker or label to their distributors so they can be applied at the point of sale. PAR 1146.2 is proposing a labeling requirement under

the new subdivision (j) for the period between the new building compliance date and the existing building compliance date of an equipment category, and the extended period for tankless water heaters being installed in mobile homes.

Paragraph (j)(1) – Labeling Schedule

Pursuant to the labeling schedule in Table 4, any unit that is supplied or offered for sale for use within the South Coast AQMD prior to the applicable Table 3 compliance dates that complies with the Table 1 emission limits, but not the Table 2 emission limits, shall prominently display the statement “If Installed in South Coast AQMD: For Installation and Use in Existing Buildings Only.”

Table 3-68. PAR 1146.2 Table 4 (Labeling Schedule)

Unit's Compliance Schedule	Labeling Requirements	
	Start Date	End Date
Phase I	January 1, 2026	January 1, 2029
Phase II	January 1, 2028	January 1, 2031
Phase III	January 1, 2029	January 1, 2033

Paragraph (j)(2) – Labeling for Instantaneous Water Heaters in Mobile Homes

Effective January 1, 2029, to January 1, 2033, an instantaneous water heater with rated heat input capacity of less than or equal to 200,000 Btu/hr supplied or offered for sale for use in a mobile home within the South Coast AQMD and complying with the alternative compliance date in paragraph (i)(5) shall prominently display the statement “If Installed in South Coast AQMD: For Installation and Use in Mobile Homes Only.”

Paragraph (j)(3) – Annual Reporting Requirement

Effective on and after the Table 3 compliance dates for Existing Buildings, manufacturers of natural gas-fired unit(s) shall submit a report by March 1st of the following calendar year to the Executive Officer through the compliance portal. The report shall include: 1) name of the product manufacturer; 2) list of product model(s); 3) number of units and rated heat input capacity of each model that was sold into or within the South Coast AQMD; and 4) the applicable equipment category in Table 2.

Paragraph (j)(4) – General Recordkeeping Requirement

The owner or operator of a unit shall maintain on-site a copy of the manufacturer's and/or distributor's written instructions and retain a record of the maintenance activity and fuel use records for a period of not less than three years for low-use demonstration. The owners or operators shall also maintain copy of a government-issued document (e.g., building permit) that grants permission to an individual or organization to initiate a construction project which determines the eligibility of new building or existing building for the compliance of the rule.

Paragraph (j)(5) – Rated Heat Input Capacity Documentation

The owner or operator of a unit shall maintain on-site, or provide upon the Executive Officer's request, a copy of all documents identifying the unit's rated heat input capacity including: manufacturer's or distributor's manual or invoice; and maintain documentation of the rated heat input capacity for a unit modified pursuant to paragraph (d)(5), signed by the licensed person modifying the unit, including description of all unit modifications, dates the unit was modified, and calculation of rated heat input capacity.

Paragraph (j)(6) – Recordkeeping for Alternative Compliance Option for Utility Upgrades

If an owner or operator of a unit elects to comply with the provision in paragraph (i)(1) or subparagraph (i)(2)(C), the owner or operator shall maintain records on-site, or make them available to the Executive Officer upon request, until three years after the end date of the approved extension(s), that demonstrate the power supply and the utility provider's progress on providing the necessary power, including but not limited to an official document signed by the responsible party of the utility company that services the facility that includes: an explanation of the utility upgrades required by the utility company; communications with the utility provider when the utility upgrade was requested; the estimated date the utility provider will complete the utility upgrades; additional information to substantiate that additional time is necessary; and documentation which demonstrates that the delays are outside of the reasonable control of the owner or operator.

Paragraph (j)(7) – Recordkeeping for Alternative Compliance Option for Units at a Property Under Lease

If an owner or operator of a unit elects to comply with the provision in paragraph (i)(6), the owner or operator shall maintain records on-site, or make them available to the Executive Officer upon request, until three years after reporting through the compliance portal pursuant to subparagraph (i)(6)(B), including but not limited to: a legally binding contract that explains the terms and duration of the lease under which the owner or operator of the unit is a tenant renting a property from a landlord; and documentation which demonstrates that the delays are beyond the reasonable control of the owner or operator.

Paragraph (j)(8) – Recordkeeping for Alternative Compliance Option for Construction

If an owner or operator elects to comply with the provision in paragraph (i)(7), the owner or operator shall maintain records on-site, or make them available to the Executive Officer upon request, until three years after reporting through the compliance portal pursuant to subparagraph (i)(7)(A), including but not limited to: images that show ~~the activity of~~ construction activity; ~~and the expansion of the space for the unit~~ or new location where the unit will be housed; and associated equipment by the construction; and documentation which demonstrates the construction, which could be a construction permit or contract.

Paragraph (j)(9) – Small Business Registration

If an owner or operator of a unit elects to utilize the small business exemption from paragraph (d)(3) for end of unit life replacement pursuant to paragraph (k)(5), the owner or operator must register their facility as a small business at least 90 days prior to the unit reaches its unit age, maintain related records on-site, or make them available to the Executive Officer upon request, until three years after registering through the Compliance Portal. Paragraph (j)(9) specifies the

records as business legal owner and contract information, number of current employees, the total gross annual receipts, and if the business is a non-for-profit training center.

Paragraph (j)(10) – Reporting through 1-800-CUT-SMOG®

Staff expects to establish an online reporting platform to accommodate the reporting requirements in paragraphs (i)(1), (i)(4), (i)(6), (i)(7), (j)(3), or (j)(9) prior to their effective dates. However, staff understands that there are situations where the online reporting platform might not be operational, or the owner or operator of a unit cannot use the online reporting platform. Paragraph (j)(10) allows the owner or operator to report the required information by calling 1-800-CUT-SMOG® if the compliance portal is not available or not allowing entering of the necessary information, or if the owner or operator does not have the access to the compliance portal.

PAR 1146.2 Exemptions [Subdivision(k)]

Subdivision (k) has been updated to clarify exemptions and phase in new emission limits. Subdivision (k) in PAR 1146.2 was originally subdivision (h) in Rule 1146.2.

Paragraph (k)(1) – Units in Recreational Vehicles, Units Subject to Rule 1121, and Units subject to Rule 1179.1

The provisions of this rule shall not apply to units used in recreational vehicles; units subject to the limits in South Coast AQMD Rule 1121 – Control of Nitrogen Oxides from Residential Type, Natural Gas-fired Water Heaters; and units subject to a NOx emission limit in Rule 1179.1 – Emission Reductions from Combustion Equipment at Publicly Owned Treatment Works Facilities.

Paragraph (k)(2) – Low-Use Exemption – 9,000 therms per year

This existing exemption in Rule 1146.2 was intended for Type 2 units manufactured prior to January 1, 2000, with NOx emissions higher than 30 ppm NOx. The 9,000 therms per year low-use threshold is about 50 percent of typical annual fuel use for a medium size Type 2 unit, which is no longer justifiable as low-use. Staff proposes to phase out this provision when zero-emission requirements become effective.

Until the applicable Table 3 compliance dates, the Table 1 emission limits shall not apply to Type 2 units manufactured prior to January 1, 2000, that are demonstrated to use less than 9,000 therms during every calendar year. Subparagraph (g)(2)(D) addresses the recordkeeping requirements for paragraph (k)(2).

Paragraph (k)(3) – Low-Use Exemption – 2,000 or 3,000 therms per year

Paragraph (k)(3) provides a new low-use exemption from Table 2 zero-emission requirements for existing units installed prior to the date of rule adoption. Annual use of 3,000 therms is about 16 percent normal fuel use for a 1 MMBtu/hr unit and 2,000 therms is about 27 percent normal fuel use for a 400 kBtu/hr unit. The provisions of paragraphs (d)(2) and (d)(3) and subparagraph (d)(5)(B) shall not apply to the following existing units installed prior to the date of rule adoption that meet Table 1 emission limits: units with a rated heat input capacity greater than 1 MMBtu/hr, but less than or equal to 2 MMBtu/hr that are demonstrated to use less than 3,000 therms during every calendar year; or units with a rated heat input capacity greater than 400 kBtu per hour, but less than or equal to 1 MMBtu/hr that are demonstrated to use less than 2,000 therms during every calendar year. Subparagraph (g)(2)(D) addresses the recordkeeping requirements for paragraph (k)(3).

Paragraph (k)(4) – Residential Structures

The provisions of paragraphs (d)(3), (d)(4), (d)(5), (d)(6), (d)(7) and the recordkeeping and reporting provisions in paragraphs (j)(4) through (j)(9) shall not apply to units installed or used for residential structures. The retrofit requirement is intended for installations in industrial and commercial settings; therefore, units for residential structures are exempted from this requirement.

Paragraph (k)(5) – Zero-Emission for Existing Units after Their Unit Age for Small Businesses

The provisions of paragraph (d)(3) shall not apply to units installed in facilities that meet the Rule 102 definition of a small business if the owners or operators of the units register their facilities as small businesses and meet the specified recordkeeping requirements.

Paragraph (k)(6) – Certification Requirements

Certification requirements specified in paragraphs (f)(1) through (f)(4) shall not apply to units complying with Table 2 emission limits.

CHAPTER 4: IMPACT ASSESSMENT

INTRODUCTION

EMISSIONS INVENTORY AND EMISSION REDUCTIONS

COST-EFFECTIVENESS ~~AND INCREMENTAL COST-EFFECTIVENESS~~

SOCIOECONOMIC IMPACT ASSESSMENT

**CALIFORNIA ENVIRONMENTAL QUALITY ACT (CEQA) ANALYSIS
SUMMARY**

**DRAFT FINDINGS UNDER HEALTH AND SAFETY CODE SECTION
40727**

COMPARATIVE ANALYSIS

INTRODUCTION

PAR 1146.2 is expected to impact 1,070,000 units located in the South Coast AQMD region.

EMISSIONS INVENTORY AND EMISSION REDUCTIONS

The total NO_x inventory for the RECLAIM and non-RECLAIM units affected by PAR 1146.2 is estimated to be 5.6 tpd. For context, the 2022 AQMP indicated a total of 351 tpd of NO_x emitted from all sources in the region in 2018, the base-year of the emissions inventory and modeling analysis in the plan. Appliances used in residential and commercial buildings emit about 22.1 tpd of NO_x, which is about 54 percent of 2037 NO_x emissions from all stationary and area sources that South Coast AQMD regulates. Those appliances are primarily space and water heaters, cooking devices, and some other appliances combusting natural gas. The estimated baseline emissions for PAR 1146.2 are around nine percent of the total stationary source inventory, as shown in the figure below.

Figure 4-1. 2018 NO_x Emissions from Stationary Sources (tons per day)

Baseline Emissions

PAR 1146.2 will impact 1,070,000 units, the applicable large water heaters, small boilers, and process heaters. To estimate baseline emissions, staff evaluated the following information:

- Estimated universe by category and categories' percentage of universe
- Unit size (MMBtu/hr) of the gas unit being replaced in each category
- Baseline Emission Factor (lb/MMBtu)
- Capacity Factor (or Usage Factor)
- Unit Age (years)

The following table was presented in Working Group Meeting #5 and has since been updated to reflect new data and assumptions:

Table 4-1. Baseline Emission Estimates

Equipment Category	Estimated Universe	Baseline Emissions Estimate (tpd)
Type 1 Units (not Type 1 Pool Heaters, Instantaneous Water Heaters, or High Temperature Units)	60,000	0.50
Type 1 High Temperature Units		0.19
Type 2 Units (not Instantaneous Water Heaters)		1.39
Type 1 Pool Heaters	710,000	3.25
Instantaneous Water Heaters	300,000	0.28
Total	1,070,000	5.61

Staff estimated the Type 1 pool heater universe and updated the baseline emission estimate in Working Group Meeting #5. According to the 2019 CEC Residential Appliance Saturation Study (RASS), seven percent of homes in the SoCalGas region have spas with gas heaters and five percent have pools with gas heaters.⁵⁴ There are approximately 5.9 million homes in the region from the U.S. Census' 2021 American Housing Survey. Staff estimated approximately 710,000 Type 1 pool heaters in the region and baseline emissions of 3.25 tpd for this category as 5.9 million homes \times 0.12 = 708,000, rounding to 710,000. Based on the U.S. DOE estimate for units in California and the new DOE 84% efficiency requirement for gas pool heaters by 2028, staff calculated 211 annual operating hours for pool and spa heater units in California. Staff had previously used a capacity factor of 7.16% or 627 operating hours based on the previous Rule 1146.2 2004 implementation study, and staff had previously used 95% for gas pool heater efficiency. The updated pool and spa heater universe, annual operating hours of 211, and 84% pool heater efficiency inform the pool heater baseline emission estimate of 3.25 tpd, which is lower than the previous estimate of 5.66. This affects the total baseline emission estimate for PAR 1146.2 which is updated to 5.61 tpd.

⁵⁴ 2019 CEC Residential Appliance Saturation Study, Page 11, Table ES-3: Natural Gas UECs and Appliance Saturation Summaries by Gas Utility, <https://www.energy.ca.gov/data-reports/surveys/2019-residential-appliance-saturation-study>

Figure 4-2. Percent of Baseline NOx Emissions Estimate

Analysis during the 2006 rule amendment estimated around 40,000 Type 1 units and 22,000 Type 2 units in the South Coast AQMD based on data provided by SoCalGas. For PAR 1146.2, staff updated the Type 1 and Type 2 water heater and boiler categories' percentages of universe based on Air-Conditioning, Heating, and Refrigeration Institute (AHRI) certifications data. Staff estimates there are approximately 60,000 Type 1 and Type 2 water heaters and boilers.

In recent years, adoption of residential instantaneous water heaters has increased with state and federal energy efficiency regulations. Staff estimated the instantaneous water heater universe to be approximately 300,000 instantaneous water heaters in the South Coast AQMD region using the 2019 California Residential Appliance Saturation Study (RASS) from the CEC and the Residential Energy Consumption Survey (RECS) from the U.S. Energy Information Administration.^{55,56}

The baseline emission was estimated per unit by category as: Lifetime NOx Baseline Emission (tons) = Unit Size (MMBtu/hr) × Baseline Emission Factor (lb/MMBtu) × Capacity Factor (or usage factor) × Annual Hours × Unit Age (years) ÷ 2,000 pounds per ton.

For Type 1 units and instantaneous water heaters, 0.238 MMBtu/hr was the Type 1 mid-range unit size utilized in the calculation. For Type 2 units (not instantaneous water heaters), 1.2 MMBtu/hr was the Type 2 mid-range unit size utilized in the calculation.

The baseline emission factor (pounds per MMBtu) taken from previous Rule 1146.2 rulemaking was 0.067 pound of NOx per MMBtu for 20 ppmv at ~~3%~~three percent oxygen for Type 1 pool

⁵⁵ California Energy Commission, 2019 California Residential Appliance Saturation Study, <https://www.energy.ca.gov/publications/2021/2019-california-residential-appliance-saturation-study-rass>

⁵⁶ U.S. Energy Information Administration, 2020 Residential Energy Consumption Survey Data, <https://www.eia.gov/consumption/residential/data/2020/>

heaters and 0.024 pound of NO_x per MMBtu for 20 ppmv at ~~3%~~three percent oxygen for other categories.

The analysis also assumed 100 percent emission reduction for zero-emission units. The estimated emission reduction is 5.61 tpd at full implementation. For context, the 2022 AQMP indicated a total of 351 tpd of NO_x emitted in 2018, the base-year of the emissions inventory and modeling analysis in the plan.

Zero-Emission Co-Benefits

South Coast Air Basin has been classified as “extreme” nonattainment for the 2015 ozone standard. Ozone is formed when NO_x and VOC react in the presence of sunlight. While both NO_x and VOC contribute to ozone, the key to attaining the ozone standard in the Basin is to reduce NO_x.⁵⁷ While PAR 1146.2 is focused on zero-NO_x standards, air quality co-benefits of zero-emission standards include reducing other emissions such as greenhouse gas (GHG) and particulate matter (PM) emissions. CARB’s current rulemaking for potential statewide zero-emission appliance standards would be focused on zero-GHG and zero-NO_x, while also quantifying the air quality co-benefits of reducing criteria pollutants such as smog-forming NO_x, CO, and toxic air contaminant emissions.⁵⁸ The PAR 1146.2 zero-emission standard will also be considered as a control strategy for the South Coast AQMD to attain the 2012 annual PM 2.5 national ambient air quality standard by 2030.

COST-EFFECTIVENESS

Health and Safety Code Section 40920.6 requires a cost-effectiveness analysis when establishing BARCT requirements. The cost-effectiveness of a control technology is measured in terms of the control cost in dollars per ton of air pollutant reduced ~~is measured in terms of the control cost in dollars per ton of air pollutant reduced~~ for each class and category of equipment. The costs for the control technology include purchasing, installation, operating, and maintaining the control technology.

As detailed in ~~e~~Chapter ~~two~~2, the South Coast AQMD typically relies on the DCF method which converts all costs, including initial capital investments and costs expected in the present and all future years of unit age, to a present value. The DCF calculation is detailed in Chapter 2.

The table below summarizes the cost-effectiveness estimates for each category.

⁵⁷ South Coast AQMD, 2022 AQMP, <https://www.aqmd.gov/docs/default-source/clean-air-plans/air-quality-management-plans/2022-air-quality-management-plan/final-2022-aqmp/final-2022-aqmp.pdf?sfvrsn=16>

Table 4-2. Cost-Effectiveness for PAR 1146.2 Categories

Category	Replace with	Cost-Effectiveness (\$/Ton), No Panel Upgrade		Cost-Effectiveness (\$/Ton), With Panel Upgrade	
		Energy Input Estimate Method	Energy Input Calculation Method	Energy Input Estimate Method	Energy Input Calculation Method
Type 1 Water Heater	Heat Pump	(190,000)	201,000	(93,000)	298,000
Type 2 Water Heater	Six Heat Pumps (Integrated)	(178,000)	197,000	(164,000)	212,000
	Two Heat Pumps (Split)	-	179,000	-	194,000
Type 1 Pool Heater	Heat Pump	-	11,000	-	58,000
	Heat Pump and Split Panel Cost	-	-	-	(4,000)
Type 1 High Temperature Unit	Heat Pump	-	559,000	-	578,000
	Electric Resistance	-	2,734,000	-	2,753,000
Type 2 High Temperature Unit (1 MMBtu)	Heat Pump	-	257,000	-	264,000
	Electric Resistance	-	2,722,000	-	2,812,000
Type 2 High Temperature Unit (2 MMBtu)	Heat Pump	-	152,000	-	156,000
Instantaneous Water Heater	Heat Pump	(185,000)	101,000	12,000	298,000
	Heat Pump and Split Panel Cost	-	-	(63,000)	223,000
	Electric Resistance Tank Type	-	3,078,000	-	3,275,000
	Electric Resistance Instantaneous	-	3,123,000	-	3,320,000

The proposed BARCT emission limits will take effect at the end of the presumed unit age of the equipment that is currently being used; therefore, the majority of the cost impacts are at the natural turnover of the equipment. The facilities will incur some cost to upgrade the equipment, but some of the cost will already be incurred due to end-of-unit-age replacement.

SOCIOECONOMIC IMPACT ASSESSMENT

Health and Safety Code Section 40440.8 requires a socioeconomic impact assessment for proposed and amended rules resulting in significant impacts to air quality or emission limitations. A Draft Socioeconomic Impact Assessment for PAR 1146.2 has been prepared and released for public review and comment on May 7, 2024. The Final Socioeconomic Impact Assessment is available in Attachment H of the June 7, 2024, Governing Board Package.

CALIFORNIA ENVIRONMENTAL QUALITY ACT (CEQA) ANALYSIS SUMMARY

Pursuant to the California Environmental Quality Act (CEQA) and South Coast AQMD's certified regulatory program (Public Resources Code Section 21080.5, CEQA Guidelines Section 15251(l) and South Coast AQMD Rule 110), the South Coast AQMD, as lead agency, reviewed the proposed project (PAR 1146.2) and determined that: 1) PAR 1146.2 implements the 2022 AQMP Control Measure C-CMB-01 – Commercial Water Heating; and 2) the Final Program Environmental Impact Report (EIR) for the 2022 AQMP evaluated Control Measure C-CMB-01 and analyzed its potential environmental impacts. Since PAR 1146.2 does not involve any new or modified impacts when compared to what was previously analyzed in the Final Program EIR for Control Measure C-CMB-01, PAR 1146.2 qualifies as a later activity within the scope of the program approved earlier for the 2022 AQMP per CEQA Guidelines 15168 (c), and the Final Program EIR for the 2022 AQMP adequately describes the activity for the purposes of CEQA such that no new environmental document will be required. The detailed CEQA analysis supporting this conclusion is provided in Appendix A of this staff report.

DRAFT FINDINGS UNDER HEALTH AND SAFETY CODE SECTION 40727

Requirements to Make Findings

Health and Safety Code Section 40727 requires that prior to adopting, amending, or repealing a rule or regulation, the South Coast AQMD Governing Board shall make findings of necessity, authority, clarity, consistency, non-duplication, and reference based on relevant information presented at the public hearing, and in the staff report.

Necessity

PAR 1146.2 is needed to establish BARCT requirements and achieve emission reductions proposed by 2022 AQMP Control Measure C-CMB-01 in order to meet the National Ambient Air Quality Standards for ozone.

Authority

The South Coast AQMD Governing Board has authority to adopt amendments to Rule 1146.2 pursuant to Health and Safety Code Sections 39002, 40000, 40001, 40440, 40702, 40725 through 40728, and 41508.

Clarity

PAR 1146.2 is written or displayed so that its meaning can be easily understood by the persons directly affected by it.

Consistency

PAR 1146.2 is in harmony with, and not in conflict with or contradictory to, existing statutes, court decisions, or state or federal regulations.

Non-Duplication

PAR 1146.2 will not impose the same requirements as any existing state or federal regulations. The proposed amended rule is necessary and proper to execute the powers and duties granted to, and imposed upon, the South Coast AQMD.

Reference

In amending Rule 1146.2, the following statutes which the South Coast AQMD hereby implements, interprets, or makes specific are referenced: Health and Safety Code Sections 39002, 40000, 40001, 40440, 40702, 40725 through 40728, and 41508.

COMPARATIVE ANALYSIS

Under Health and Safety Code Section 40727.2, the South Coast AQMD is required to perform a comparative analysis when adopting, amending, or repealing a rule or regulation. The comparative analysis is relative to existing federal requirements, existing or proposed South Coast AQMD rules and air pollution control requirements and guidelines which are applicable to combustion equipment subject to PAR 1146.2. There is no equivalent federal regulation applicable to be included in the table below.

Table 4-3. Comparative Analysis

Rule Element	Rule 1121	PAR 1146.2	Rule 1146.1	Rule 1146	Bay Area AQMD Rule 9-6	CARB In-Progress Rulemaking
Applicability	Natural gas-fired water heaters with heat input rates less than 75 kBtu/hr	Large water heaters, small boilers and process heaters less than or equal to 2 MMBtu/hr	Boilers, steam generators, and process heaters with maximum rated heat input capacities greater than 2 MMBtu/hr and less than 5 MMBtu/hr	Boilers, steam generators, and process heaters with maximum rated heat input capacities greater than or equal to 5 MMBtu/hr	Natural gas-fired water heater, rated heat input capacity 75 kBtu/hr – 2 MMBtu/hr	TBD: Anticipated 2030 for new equipment and appliances sold for use in both residential and commercial buildings
Requirements (All parts per million (ppmv) emission limits are referenced at three percent volume stack gas oxygen on a dry basis averaged over a period of 15 consecutive minutes)	NOx limits: Natural gas: 15 ppmv	NOx and CO limits: Natural gas: 0 ppmv (zero-emission)	NOx limits: Digester gas: 15 ppmv Landfill gas: 25 ppmv Natural gas: 7 or 9 ppmv, 12 ppmv for atmospheric, and 12 ppmv for thermal fluid heaters All others: 30 ppmv CO limit: 400 ppmv	NOx limits: Digester gas: 15 ppmv Landfill gas: 25 ppmv Natural gas: 5 ppmv for ≥ 75 MMBtu/hr, 7 or 9 ppmv for 20–75 MMBtu/hr, 12 ppmv for atmospheric, and 12 ppmv for thermal fluid heaters For other types of fuels: 30 ppmv for other gaseous fuels; 40 ppmv for nongaseous fuels CO limit: 400 ppmv	NOx limits: Natural gas: 0 ppmv (zero-emission)	TBD: Anticipated zero-emission (GHG, NOx)
Reporting	None	Manufacturers every year	None	Every 6 months for units greater	None	TBD

Rule Element	Rule 1121	PAR 1146.2	Rule 1146.1	Rule 1146	Bay Area AQMD Rule 9-6	CARB In-Progress Rulemaking
		after Table 3 compliance dates – product models, unit number, rated heat input capacity, applicable equipment category		than or equal to 40 MMBtu/hr and an annual heat input greater than 200 x 10 ⁹ Btu per year (Rule 218)		
Monitoring	None	Source test report Requirements by alternative compliance options	Source testing once every 5 years	A continuous in-stack NO _x monitor for units greater than or equal to 40 MMBtu/hr and an annual heat input greater than 200 x 10 ⁹ Btu per year Source testing once every 3 – 5 years for other units	None	TBD
Recordkeeping	None	Maintenance records = 3 years Rated heat input capacity & modification documentation	Source test records = 2 years (5 years if Title V) Monitoring data = 2 years (5 years if Title V)	Source test records Maintenance & emission records = 2 years Monitoring data = 2 years (5 years if Title V)	None	TBD

APPENDIX A: DETAILED CEQA ANALYSIS

INTRODUCTION

INTRODUCTION

The California Environmental Quality Act (CEQA) is comprised of Public Resources Code Section 21000 et seq. and the CEQA Guidelines which are codified at Title 14 California Code of Regulations, Section 15000 et seq. CEQA requires the evaluation of all potential adverse environmental impacts of proposed projects and the identification and implementation of methods to reduce or avoid significant adverse environmental impacts of these projects, if feasible. [Public Resources Code Section 21061.1 and CEQA Guidelines Section 15364 defining feasible]. The purpose of the CEQA process is to inform decision makers, public agencies, and interested parties of potential adverse environmental impacts that could result from implementing a proposed project and to identify feasible mitigation measures or alternatives, when an impact is significant.

Control Measure C-CMB-01 of the 2022 AQMP seeks to deploy zero-emission water heating units for new and existing commercial buildings. South Coast AQMD is technology and fuel neutral, and is focused on achieving NO_x emission reductions. Should zero-NO_x natural gas technologies be developed and adopted, consumers would have the opportunity to choose between newly designed natural gas and other zero-emission appliances. The zero-emission water heating units with high energy efficiency appropriate for use in commercial applications could be integrated heat pump water heaters, which have water tanks packaged with them as single units, or split heat pump water heaters with water tanks located up to 50 feet away. These devices would increase electricity demand.

PAR 1146.2 implements Control Measure C-CMB-01 of the 2022 AQMP and proposes to achieve NO_x emission reductions by requiring zero-emission (0 ppmv) limits for new installations based on future effective dates depending on the commercial availability of zero-emission technologies, and zero-emission limits for existing units that will reach the end of unit age after the zero-emission compliance dates, with an exemption for units used for residential structures and small businesses. PAR 1146.2 affects approximately 1,070,000 units in the South Coast AQMD jurisdiction, and full implementation of PAR 1146.2 is expected to reduce NO_x emissions by 5.6 tons per day (tpd) by 2058. A technology assessment by ~~January 1, 2028~~[June 1, 2027](#) would provide the Stationary Source Committee with an update on the technology and market readiness for the rule.

The 2022 AQMP⁵⁹ was considered a “project” as defined by CEQA Guidelines Section 15378, and the South Coast AQMD was lead agency under CEQA because it was the “public agency that has the principal responsibility for carrying out or approving a project that may have a significant effect upon the environment.” [Public Resources Code Section 21067]. Further, since the South Coast AQMD Governing Board had the primary responsibility for approving the entirety of the project, the South Coast AQMD was the most appropriate public agency to act as lead agency for the project. [CEQA Guidelines Section 15051(b)].

The 2022 AQMP: 1) had environmental impacts which were evaluated in a Final Program Environmental Impact Report (Program EIR); and 2) was a discretionary action which was considered and approved by the South Coast AQMD Governing Board.

⁵⁹ South Coast AQMD, 2022 Air Quality Management Plan, December 2022. <https://www.aqmd.gov/home/air-quality/air-quality-management-plans/air-quality-mgt-plan>

Therefore, the proposed project, PAR 1146.2, is integrally related to the 2022 AQMP for which a previous environmental analysis has been prepared in the Final Program EIR for 2022 AQMP, which was certified by the South Coast AQMD Governing Board on December 2, 2022.⁶⁰

The Final Program EIR for the 2022 AQMP identified potentially significant impacts, and mitigation measures were adopted. Further, since mitigation measures were adopted for the 2022 AQMP, a Mitigation, Monitoring, and Reporting Plan for the 2022 AQMP, pursuant to Public Resources Code Section 21081.6 and CEQA Guidelines 15097 was also required and adopted.

Further, because the Final Program EIR concluded that the 2022 AQMP will have potentially significant and unavoidable adverse impacts on the environment, Findings were made pursuant to CEQA Guidelines Section 15091, and a Statement of Overriding Considerations pursuant to CEQA Guidelines Section 15093 was adopted.

The 2022 AQMP, along with the December 2022 Final Program EIR for the 2022 AQMP (State Clearinghouse No. 2022050287) and its corresponding Findings, Statement of Overriding Considerations, and Mitigation, Monitoring, and Reporting Plan, upon which the analysis of the PAR 1146.2 relies, are incorporated by reference pursuant to CEQA Guidelines Section 15150 and are available from the South Coast AQMD's website at:

December 2022 Final Program EIR for the 2022 AQMP

Phone: (909) 396-2432
Email: publicadvisor@aqmd.gov

A Program EIR was considered to be the appropriate document for the 2022 AQMP pursuant to CEQA Guidelines Section 15168(a)(3) because the 2022 AQMP constituted a series of actions that can be characterized as one large project in connection with the issuance of rules, regulations,

⁶⁰ South Coast AQMD, Final Program Environmental Impact Report for the 2022 Air Quality Management Plan, December 2022. <https://www.aqmd.gov/docs/default-source/ceqa/documents/aqmd-projects/2022/2022-aqmp-final-peir.pdf>

plans, or other general criteria required to govern the conduct of a continuing program. In addition, the use of a Program EIR had the following advantages by:

- Providing an occasion for a more exhaustive consideration of effects and alternatives than would be practical in an EIR on an individual action;
- Ensuring a consideration of cumulative impacts that might be slighted in a case-by-case analysis;
- Avoiding duplicative reconsideration of basic policy considerations;
- Allowing consideration of broad policy alternatives and program-wide mitigation measures at an early time when the Lead Agency has greater flexibility to deal with basic problems of cumulative impacts; and
- Allowing its use with a later activity if the later activity is within the scope of the project analyzed in the Program EIR without requiring further environmental documents.

Because PAR 1146.2 implements a previously adopted 2022 AQMP Control Measure C-CMB-01, this chapter examines whether PAR 1146.2 qualifies as a later activity within the scope of the analyses in the Final Program EIR for the 2022 AQMP, pursuant to CEQA Guidelines 15168(c) – Use with Later Activities.

As such, this chapter: 1) compares the proposed later activity of PAR 1146.2 with the previously approved program, Control Measure C-CMB-01 which was adopted in the 2022 AQMP; 2) summarizes the environmental impacts analyzed in the Final Program EIR for the 2022 AQMP for Control Measure C-CMB-01; 3) identifies the differences, if any, between the analysis of the environmental impacts in the Final Program EIR for 2022 AQMP for Control Measure C-CMB-01 and PAR 1146.2 and as needed, identifies any other impact areas which may require further analysis; and 4) considers the evidence and determines whether: a) PAR 1146.2 is a later activity within the scope of the program approved earlier for the 2022 AQMP; and b) the Final Program EIR for the 2022 AQMP adequately describes the later activity of PAR 1146.2 for the purposes of CEQA such that no new environmental document will be required.

SUMMARY OF ENVIRONMENTAL IMPACTS

The CEQA Guidelines require environmental documents to identify significant environmental effects that may result from a proposed project. [CEQA Guidelines Section 15126.2(a)]. Direct and indirect significant effects of a project on the environment should be identified and described, with consideration given to both short- and long-term impacts. The discussion of environmental impacts may include, but is not limited to, the resources involved; physical changes; alterations of ecological systems; health and safety impacts caused by physical changes; and other aspects of the resources involved including water, scenic quality, and public services. If significant adverse environmental impacts are identified, the CEQA Guidelines require a discussion of measures that could either avoid or substantially reduce any adverse environmental impacts to the greatest extent feasible. [CEQA Guidelines Section 15126.4].

The categories of environmental impacts to be studied in a CEQA document are established by CEQA [Public Resources Code Section 21000 et seq.] and the CEQA Guidelines [codified in Title

14 California Code of Regulations Section 15000 et seq]. Under the CEQA Guidelines Appendix G: Environmental Checklist Form, there are 20 environmental topic areas categories in which potential adverse impacts from a project are evaluated. The South Coast AQMD, as lead agency, has taken into consideration the environmental checklist questions in Appendix G, but has reorganized the contents to consolidate the environmental topic areas to avoid repetition. For example, South Coast AQMD's customized the environmental checklist by: 1) combining the topics of "air quality" and "greenhouse gas emissions" into one section; 2) combining the topics of "cultural resources" and "tribal cultural resources" into one section; 3) separating the "hazards and hazardous materials" topic into two sections: "hazards and hazardous materials" and "solid and hazardous waste;" and 4) distributing the questions from the topic of "utilities/service systems" into other more specific environmental areas such as "energy," "hydrology and water quality," and "solid and hazardous waste." For each environmental topic area, per CEQA Guidelines Section 15064.7(a), "[a] threshold of significance is an identifiable quantitative, qualitative, or performance level of a particular environmental effect, noncompliance with which means the effect will normally be determined to be significant by the agency and compliance with which means the effect normally will be determined to be less than significant." The South Coast AQMD has developed unique thresholds of significance for the determination of significance in accordance with CEQA Guidelines Section 15064.7(b).

The CEQA Guidelines also includes provisions for the preparation of Program EIRs in connection with the issuance of plans, such as the 2022 AQMP, to govern the conduct of a continuing program, including adoptions of broad policy programs as distinguished from those prepared for specific types of projects such as land use projects, for example. [CEQA Guidelines Section 15168]. A Program EIR also allows for the consideration of broad policy alternatives and program-wide mitigation measures at an early time when an agency has greater flexibility to deal with basic problems or cumulative impacts. [CEQA Guidelines Section 15168 (b)(4)]. Lastly, a Program EIR also plays an important role in establishing a structure within which a CEQA review of future related actions can be effectively conducted. A Program EIR, by design, provides the basis for future environmental analyses and will allow future project-specific CEQA documents, if necessary, to focus solely on the new effects or detailed environmental issues not previously considered. If an agency finds that no new effects could occur, or no new mitigation measures would be required, the agency can approve the activity as being within the scope of the project covered by the Program EIR and no new environmental document would be required. [CEQA Guidelines Section 15168(c)(2)].

The Final Program EIR for the 2022 AQMP analyzed the impacts of implementing the various control measures in the 2022 AQMP on 19 environmental topic areas: aesthetics, agriculture and forestry resources, air quality and greenhouse gas emissions, biological resources, cultural and tribal cultural resources, energy, geology and soils, hazards and hazardous materials, hydrology and water quality, land use and planning, mineral resources, noise, population and housing, public services, recreation, solid and hazardous waste, transportation, wildfire, and mandatory findings of significance. The Final Program EIR for the 2022 AQMP concluded that the implementation of all of the control measures in the 2022 AQMP would result in potentially significant impacts for the following environmental topic areas: air quality and greenhouse gas (GHG), energy, hazards and hazardous materials, hydrology and water quality, noise, and solid and hazardous waste. All other environmental topic areas were either concluded to have less than significant impacts or no impact. Mitigation measures to minimize significant impacts from implementation of the 2022

AQMP were adopted in the Mitigation, Monitoring, and Reporting Plan which can be found in Attachment 1 to the Governing Board Resolution for the Final Program EIR for the 2022 AQMP.⁶¹

Table A-1 summarizes the analysis in the Final Program EIR for the 2022 AQMP associated with the Control Measure C-CMB-01: physical changes expected, environmental topic areas affected according to level of significance impact, and the applicable mitigation measures. It should be noted that Control Measure C-CMB-01 was determined to have potentially significant impacts to the environmental topic areas of air quality and GHG, energy, noise, and solid and hazardous waste; but no impact to the environmental topic areas of hazards and hazardous materials, and hydrology and water quality. However, the Final Program EIR for the 2022 AQMP concluded potential significant impacts to hazards and hazardous materials, and hydrology and water quality as a result of implementing other control measures.

⁶¹ South Coast AQMD, Attachment 1 to the Governing Board Resolution for the Final Program Environmental Impact Report for the 2022 Air Quality Management Plan, December 2022. <https://www.aqmd.gov/docs/default-source/ceqa/documents/aqmd-projects/2022/2022-aqmp-attachment1toresolution.pdf>

Table A-1. Analysis of Control Measure C-CMB-01 in the Final Program EIR for the 2022 AQMP

Physical Changes Expected From C-CMB-01		Environmental Topic Areas with Potentially Significant Impacts	Environmental Topic Areas with Less than Significant Impacts	Environmental Topic Areas with No Impacts	Applicable Mitigation Measures
<i>Construction</i>	Demolition or removal of existing building components or structures, and water heating systems	<ul style="list-style-type: none"> - Air Quality - Energy - Noise - Solid and Hazardous Waste 	<ul style="list-style-type: none"> - GHG - Transportation 	All other environmental topic areas not listed to be potentially significantly impacted, or less than significantly impacted	Air Quality and GHG: AQ-1 to AQ-26 Energy: E-3 to E-5, and E-7 Noise: NS-1 to NS-14 Solid and Hazardous Waste: SHW-1 to SHW-3
	Installation of new water heating systems	<ul style="list-style-type: none"> - Air Quality - Energy - Noise 			Air Quality and GHG: AQ-1 to AQ-26 Energy: E-3 to E-5, and E-7 Noise: NS-1 to NS-14
<i>Operation</i>	Increased use of electricity and natural gas to produce electricity	<ul style="list-style-type: none"> - Energy 	<ul style="list-style-type: none"> - Air Quality and GHG 		Energy: E-1 to E-4, and E-7 to E-9

Table A-2 summarizes the physical changes expected, environmental topic areas affected, and the applicable mitigation measures associated with implementation of PAR 1146.2 and compares the similarities to those analyzed for Control Measure C-CMB-01 in the Final Program EIR for the 2022 AQMP. The replacement of existing water heating equipment is expected to occur at the end of unit age such that operators will remove the existing equipment and install a new water heating system regardless of implementation of PAR 1146.2, and the upgrades to electrical panels and other building components to enable the increased use of zero-emission equipment are not expected to require trenching or other construction requiring soil movement. Therefore, of the above physical changes contemplated from Control Measure C-CMB-01, implementation of PAR 1146.2 is only expected to result in the increased use of electricity and natural gas to produce electricity.

Table A-2. Comparison of Environmental Impacts between C-CMB-01 and PAR 1146.2

Physical Changes Expected from PAR 1146.2	Similarity to Environmental Topic Areas with Potentially Significant Impacts	Similarity to Environmental Topic Areas with Less than Significant Impacts	Similarity to Environmental Topic Areas with No Impacts	Similarity to Applicable Mitigation Measures
Increased use of electricity and natural gas to produce electricity	- Energy	- Air Quality and GHG	<ul style="list-style-type: none"> - Aesthetics - Agriculture and Forestry Resources - Biological Resources - Cultural and Tribal Cultural Resources - Geology and Soils - Hydrology and Water Quality - Hazards and Hazardous Materials - Land Use and Planning - Mineral Resources - Noise - Population and Housing - Public Services - Recreation - Solid and Hazardous Waste - Transportation - Wildfire 	Energy: E-1 to E-4, and E-7 to E-9
<p><i>Because PAR 1146.2 does not require replacement of water heating systems before the end of unit age:</i></p> <p><i>1) demolition and removal of existing building components or structures, and water heating systems; and</i></p> <p><i>2) installation of new water heating systems</i></p> <p><i>are physical changes that will occur regardless of implementation of PAR 1146.2.</i></p>	<p><i>Implementation of PAR 1146.2 is expected to result in the same potentially significant impacts as anticipated for increased electrical demand from Control Measure C-CMB-01 of the 2022 AQMP.</i></p>	<p><i>Implementation of PAR 1146.2 is expected to result in the same less-than-significant impacts as anticipated for increased electrical demand from Control Measure C-CMB-01 of the 2022 AQMP.</i></p>	<p><i>Same as for increased electrical demand from Control Measure C-CMB-01</i></p>	<p><i>The mitigation measures minimizing impact on increased electricity demand from Control Measure C-CMB-01 of the 2022 AQMP are expected to apply to PAR 1146.2.</i></p>

While PAR 1146.2 implements Control Measure C-CMB-01 of the 2022 AQMP, because the proposed amended rule does not require replacement of water heating systems before the end of unit age and is not expected to require trenching or other construction requiring soil movement, the physical changes resulting from PAR 1146.2 will be fewer than those contemplated under the analysis in the Final Program EIR for the 2022 AQMP for Control Measure C-CMB-01. Further, the analysis of environmental impacts for Control Measure C-CMB-01 covers the breadth of impacts resulting from PAR 1146.2 such that no new physical impacts need to be evaluated.

The Final Program EIR for the 2022 AQMP determined that the increased electricity demand from implementation of Control Measure C-CMB-01 has the potential to generate significant adverse energy impacts, less than significant air quality and GHG impacts, and no impact to all other environmental topic areas.

ENVIRONMENTAL TOPIC AREA WITH POTENTIALLY SIGNIFICANT IMPACTS

The Final Program EIR for the 2022 AQMP analyzed the potential environmental impacts that may occur from implementing all of the control measures which comprise the 2022 AQMP and its goal to address the 2015 federal 8-hour ozone standard to satisfy the planning requirements of the federal Clean Air Act (CAA), and concluded that its implementation would result in potentially significant impacts for the following environmental topic areas: air quality and GHG, energy, hazards and hazardous materials, hydrology and water quality, noise, and solid and hazardous waste. Specific to the implementation of Control Measure C-CMB-01, the Final Program EIR for the 2022 AQMP analyzed and concluded potentially significant impacts to the environmental topic of energy.

Since PAR 1146.2 implements Control Measure C-CMB-01 without adding new or modifying the previously analyzed impacts for each environmental topic area, the overall conclusion of potentially significant impacts for the topic of energy in the Final Program EIR for the 2022 AQMP will remain unchanged if PAR 1146.2 is implemented.

The following section summarizes the analysis of potentially significant impacts for the topic of energy in the Final Program EIR for the 2022 AQMP.

Energy

The Final Program EIR for the 2022 AQMP identified the following potential significant energy impacts associated with implementation of PAR 1146.2: 1) increase in electricity demand due to increased usage of zero-emission technologies installed in residential and commercial settings, and 2) increase in natural gas demand to produce electricity.

Impact to Electricity Demand

The Final Program EIR for the 2022 AQMP estimated potential electricity use associated with residential and commercial water heating where sufficient data was available to make reasonable estimates. Table A-3 is a subset of Table 4.3-2. Potential Increase in Electricity Use for Residential and Commercial Equipment, from the Final Program EIR for the 2022 AQMP.

Table A-3. Potential Increase in Electricity Use for Residential and Commercial Water Heating Estimated in the Final Program EIR for the 2022 AQMP

Equipment/ Source Category	Estimated Number of Affected Units	Estimated Electricity Use Per Unit ⁽¹⁾	Estimated Total Electricity Use (GWh/yr)
Residential Water Heating	Of 2 million water heaters installed, 50% of residences will be zero-emission and 50% will be low NOx water heaters ⁽²⁾	380 - 500 kWh/month	6,000
Residential – Other Combustion Sources (pool heaters)	200,000 pool heaters ⁽³⁾	1.5 kWh/hr	60
Commercial Water Heating	96,000 ⁽⁴⁾ : 64,000 Tier I (less than 400 kBTU/hr) 32,000 Tier II (400 kBTU/hr to 2 MMBTU/hr)	Tier I: 1.4 kWh/hr Tier II: 6.8 kWh/hr	Tier I: 98 Tier II: 238

Source: Final Program EIR for the 2022 AQMP, see Chapter 4, page 4.3-11, Table 4.3-2.

(1) <https://www.siliconvalleypower.com/residents/save-energy/appliance-energy-use-chart>.

(2) For purposes of calculating maximum electricity increases, all new units are assumed to be third-party provided power even though some portions will be solar powered.

(3) Assumes pool heaters are used 200 hours per year.

(4) Assumes water heaters operates 3 hours per day.

While Table A-3 presents estimates on the total electricity use from residential water heaters and pool heaters, and commercial water heaters, the Final Program EIR for the 2022 AQMP considered Basin-wide electricity use to form its conclusion regarding energy impacts due to electricity demand. Statewide electricity consumption was more than 279,000 GWh in 2020, with approximately 118,200 GWh (42 percent) in the South Coast Air Basin. [CEC, 2021]. CEC estimated an increase in electricity demand of about 1.6 percent annually through 2035. [CEC, 2021]. By applying that growth rate, the total electricity use in California would be approximately 354,000 GWh by 2035. Approximately 150,000 GWh (42 percent) of that would be within the South Coast Air Basin (assuming the percentage attributed to the South Coast Air Basin remains the same). The 2022 AQMP control measures would then increase the electricity demand by an additional estimated 13,429 GWh (approximately 11 percent over 2020 consumption and nine percent over the CEC projected growth) and this amount did not take into account the electricity that may be needed to operate additional air pollution control equipment or to convert combustion equipment to fully electric. Thus, the overall potential increase in electricity demand could be higher.

In order for utilities to be able to provide sufficient electricity to meet future demands, the use of additional energy storage systems (e.g., battery arrays) is also a key component for being able to store electricity at the time when resources are available (e.g., when the sun shines and the wind blows), and to use that stored electricity at a later time. Further, the analysis in the Final Program EIR for the 2022 AQMP conservatively assumed that all sources affected by a control measure with the potential to increase demand for electricity, would use electricity rather than other forms

of energy. In addition, any increase in electricity demand would likely result in a concurrent reduction in demand for other types of fuels, particularly petroleum fuels. Because the control measures in the 2022 AQMP were developed with the goal of attaining the federal ozone standard, the successful implementation of some of the control measures relied on the use of electricity in order to reduce NOx emissions, an overall air quality benefit for the region. Therefore, the 2022 AQMP was expected to result in a substantial depletion of existing energy (specifically electricity) resource supplies.

Even with energy conservation programs in effect in California, additional electricity would be needed, and power plants would be required to supply the projected increase in electricity demand and general population growth. While increased demand for electricity would occur due to general population growth, additional increases in electricity demand beyond general population growth would be expected if the control measures in the 2022 AQMP, such as C-CMB-01, were implemented. The implementation of all the control measures was expected to result in an overall increase of greater than the approximately 11 percent of the existing electricity use discussed for residential, commercial, and mobile sources. This increase, along with the increases in electricity associated with other state programs and mandates, was expected to exceed the electrical generating capacity of the system. Thus, the energy impacts from the implementation of the 2022 AQMP were expected to be significant for electricity demand.

Because the energy impacts from the implementation of the 2022 AQMP are expected to be significant for electricity demand, the Final Program EIR for the 2022 AQMP provided feasible mitigation measures E-1 to E-7 for reducing impacts related to potential electricity demand. Because mitigation measure E-5 minimizes impacts from charging electric vehicles and mobile sources, and mitigation measure E-6 pertains to use of electrical transportation systems, and these two sources are not affected by Control Measure C-CMB-01, only mitigation measures E-1 to E-4, and E-7 are applicable to minimizing energy impacts from increased electricity demand due to implementation of PAR 1146.2.

The Final Program EIR for the 2022 AQMP concluded that significant adverse electricity demand impacts would be created by the 2022 AQMP because the potential increase in electricity usage would exceed baseline electricity consumption by up to 11 percent. Even after mitigation measures E-1 to E-7 were applied, electricity demand impacts would remain significant.

The data in Table A-3 is extracted from Table 4.3-2 of the Final Program EIR for the 2022 AQMP and was forecasted based on the best information available at the time. Development of PAR 1146.2 has clarified that there are currently 708,000 existing pool and spa heaters in the South Coast Basin, and that each of these pool and spa heaters operate approximately 211 hours per year. If all 708,000 of the pool and spa heaters are replaced with technology that relies on electricity from the power grid, then the energy use estimate will increase from 60 GWh/year to 224 GWh/year. Overall, this change in the number of pool and spa heaters would increase the electricity demand from all 2022 Control Measures from 13,429 GWh (approximately 11 percent over 2020) to 13,593 GWh (approximately 11.5 percent over 2020 consumption).

Thus, this projected increase in the number of affected equipment from 200,000 pool heaters to 708,000 pool and spa heaters, and the increase in the operating hours per year from 200 to 211 does not substantially change the overall energy impacts analysis or conclusions, because: 1) the

Final Program EIR for the 2022 AQMP already considered an 11% increase in overall Basin-wide use of electricity at a minimum, stating that overall potential electricity use for all control measures implemented together could be higher; 2) PAR 1146.2 does not specify the type of technology that may be employed to achieve the NO_x emission standards so solar pool and spa heaters may be part of the technology mix which if employed, would mean electricity sourced from the power grid may not be needed for the entire universe of existing pool and spa heaters being replaced and that the locations relying on solar technology would have a lesser demand for electricity that is sourced from the grid; 3) pool and spa heaters are typically used in the colder months and evenings which is generally outside of peak daily electricity demand; and 4) the timing when pool and spa heaters are expected to be replaced will occur over an extended implementation schedule between 2031 and 2046. Implementation of the 2022 AQMP was concluded to have significant energy impacts due to electricity demand, and based on the preceding update to the analysis, the increase in number of potentially affected units and operating hours does not change this conclusion.

Impact to Natural Gas Demand

Control measures in the 2022 AQMP, such as C-CMB-01, were expected to result in: 1) an increase in demand for natural gas primarily associated with the production of electricity in the short term; and 2) a decreased demand for natural gas appliances in commercial and residential setting. Control measure C-CMB-01 was expected to require additional electricity. While the electrical grid needs to generate electricity that is comprised of 100 percent renewable energy by 2045 per Senate Bill 100 (SB 100, De León)⁶² (and short-term natural gas usage for the production of electricity will cease), additional sources of electricity would be required in order to meet the 2035 goals of the 2022 AQMP.

The potential for growth in electrification poses considerable uncertainty on when, where, and how large the impact on natural gas demand in California will be. For the residential and commercial building sectors, electrification of various appliances such as water heating would have the potential to decrease the use of natural gas. However, while there will be a shift from utilizing natural gas in these types of appliances for residential and commercial land uses to electricity, the potential for increased electrification of buildings would also contribute to an overall increase in electricity demand which could require natural gas-fired turbines and engines to ramp up operations to meet the increased load. This load increase could cause additional use of natural gas in electricity generation equipment. [California Gas and Electric Utilities, 2020].

SoCal Gas projects total gas demand to decline at an annual rate of one percent between 2020 and 2035. The decline in natural gas demand is due to modest economic growth and California Public Utilities Commission (CPUC)-mandated energy efficiency standards and programs. Other factors that contribute to the downward trend are more stringent standards established in the revised Title 24 Building Codes, renewable electricity goals, a decline in core commercial and industrial demand, and conservation savings. [California Gas and Electric Utilities, 2020].

There are critical interdependencies between electricity and the natural gas system reliability in California. Natural gas-fired electricity generation has been an integral part of the electricity system, providing baseload power. It has also served as the backstop during drought conditions that reduce the availability of hydroelectric power generation. The role of natural gas-fired

⁶² Senate Bill 100, https://leginfo.ca.gov/faces/billTextClient.xhtml?bill_id=201720180SB100.

electricity generation in the electricity system is shifting with the addition of large amounts of renewable generation, primarily solar and wind. The large influx of renewable energy on the grid has reduced natural gas produced electricity from 53 percent of total electric generation in 2010 to 48 percent in 2020. Renewables have displaced a portion of daytime generation previously provided by natural gas, but the intermittency of solar and wind resources necessitates flexible resources that can quickly come on-line when the sun sets, or winds stop blowing. [CEC, 2021].

Total electric generation load (including large cogeneration and non-cogeneration electric generation for a normal hydro year) is expected to decline from 245 billion cubic feet in 2020 to 182 billion cubic feet in 2035, a decrease of 2.0 percent per year. The main factors for the decline are an increasing renewable energy target level, retirement of older natural gas-fired plants, and the addition of more efficient natural gas-fired plants. [California Gas and Electric Utilities, 2020].

Ultimately, as natural gas is generally widely available, natural gas supplies were not expected to be limited if the 2022 AQMP was implemented. The combined increase in natural gas demand needed for producing electricity and hydrogen and for fueling vehicles could be somewhat offset over the long-term by a decrease in demand for natural gas appliances in commercial and residential settings. However, over the short term, the natural gas demand was expected to increase. Based upon these considerations, significant adverse energy impacts relating to natural gas demand were expected from implementing the 2022 AQMP.

Because the energy impacts from the implementation of the 2022 AQMP are expected to be significant for natural gas demand, the Final Program EIR for the 2022 AQMP provided the feasible mitigation measures E-8 to E-9 for reducing impacts related to potential natural gas demand.

The Final Program EIR for the 2022 AQMP concluded that significant adverse natural gas demand impacts would be created by the 2022 AQMP because of the potential increase in natural gas usage for electricity and hydrogen production. Even after mitigation measures E-8 and E-9 were applied, natural gas demand impacts would remain significant.

Mitigation Measures

- E-1 Project sponsors should pursue incentives to encourage the use of energy efficient equipment and vehicles and promote energy conservation during electricity generation.
- E-2 Utilities should increase the capacity of existing transmission lines to meet forecast demand that supports sustainable growth where feasible and appropriate in coordination with local planning agencies.
- E-3 Project sponsors should submit projected electricity calculations to the local electricity provider for any project anticipated to require substantial electricity consumption. Any infrastructure improvements necessary should be completed according to the specifications of the electricity provider.
- E-4 Project sponsors should include energy analyses in environmental documentation with the goal of conserving energy through the wise and efficient use of energy.

- E-5 Project sponsors should evaluate the potential for reducing peak energy demand by encouraging charging of electrical vehicles and other mobile sources during off-peak hours.
- E-6 Project sponsors should evaluate the potential for reducing peak energy demand by encouraging the use of catenary or way-side electrical systems developed for transportation systems to operate during off-peak hours.
- E-7 Project sponsors should evaluate the potential for reducing peak energy demand by encouraging the use of electrified stationary sources during off-peak hours.
- E-8 Projects that require a substantial increase in natural gas demand should consider the use of renewable gas, where available and feasible, including biofuel landfill gas and gas produced from renewable fuels projects.
- E-9 Project sponsors should submit projected natural gas demand use to the local natural gas provider for any project anticipated to require substantial natural gas consumption. Any infrastructure improvements necessary should be completed according to the specifications of the natural gas provider.

Cumulative Impacts

The Final Program EIR for the 2022 AQMP concluded that implementation of the 2022 AQMP could result in significant adverse electricity consumption impacts because the potential electricity usage increase would exceed baseline electricity consumption by an estimated 11 percent. Significant impacts were also concluded for natural gas and hydrogen demand. When combined with the Southern California Association of Governments (SCAG) Connect SoCal Plan⁶³, the CARB Proposed 2022 State SIP Strategy⁶⁴, state policies, and other past, present, and reasonably foreseeable activities, the 2022 AQMP would result in a significant increase in electricity, natural gas, and hydrogen demand which may not currently be available, and would contribute to cumulatively considerable impacts. No additional mitigation measures to reduce the significant cumulative impacts to energy were identified. Cumulative impacts to energy demand for past, present, and reasonably foreseeable future projects would remain significant and unavoidable for electricity, natural gas, and hydrogen demand. Because hydrogen use is not contemplated in implementation of PAR 1146.2, PAR 1146.2 does not contribute to cumulative impacts to energy from hydrogen demand.

Table A-4. Summary of Energy Analysis

Significance Criteria	Potential Significant Impacts	MMs	Cumulative Impacts
<p>Energy impacts are significant if any of the following conditions occur:</p> <ul style="list-style-type: none"> • The project conflicts with adopted energy conservation plans or standards. • The project results in substantial depletion of existing energy resource supplies. • An increase in demand for utilities impacts the current capacities of the electric and natural gas utilities. • The project uses non-renewable energy resources in a wasteful and/or inefficient manner. 	<p>Implementation of PAR 1146.2 would cause potential significant energy impacts from:</p> <ul style="list-style-type: none"> • Increase in electricity demand due to increased usage of zero-emission technologies installed in residential and commercial settings, and • Increase in natural gas demand to produce electricity 	<p>E-1 to E-4, and E-7 to E-9</p>	<p>Cumulative impacts to energy demand for past, present, and reasonably foreseeable future projects would remain significant and unavoidable for electricity and natural gas demand.</p>

ENVIRONMENTAL TOPIC AREA WITH LESS THAN SIGNIFICANT IMPACTS

Since PAR 1146.2 implements Control Measure C-CMB-01 without adding new or modifying the previously analyzed impacts for each environmental topic area, the overall conclusion of less than significant impacts for the topics of air quality and greenhouse gas emissions in the Final Program EIR for the 2022 AQMP will remain unchanged if PAR 1146.2 is implemented.

The following summarizes the analysis of less than significant impacts for the environmental topic of air quality and greenhouse gas emissions in the Final Program EIR for the 2022 AQMP.

Air Quality and Greenhouse Gas Emissions

The Final Program EIR for the 2022 AQMP concluded that implementation of the 2022 AQMP control measures, such as Control Measure C-CMB-01, would generate potentially significant air quality impacts during construction, less than significant operational air quality impacts, and potentially significant short-term increases in GHG emissions that would be offset and eventually result in a long-term net reduction in GHG emissions.

Impact to Construction Air Quality

The Final Program EIR for the 2022 AQMP contemplated that implementation of Control Measure C-CMB-01 would require construction including demolition or removal of existing building components or structures, and water heating systems, and installation of new water heating systems. These physical changes are caused by implementation of Control Measure C-CMB-01 if equipment is replaced earlier than the end of unit age. For PAR 1146.2, because replacement of existing water heating equipment is expected occur at the end of unit age such that operators will remove the existing equipment and install a new water heating system regardless of the proposed amended rule, and because upgrades to electrical panels and other building components to enable the increased use of zero-emission equipment are not expected to require trenching or other construction requiring soil movement, implementation of PAR 1146.2 is not expected to cause construction air quality impacts.

Impact to Operational Air Quality

The Final Program EIR for the 2022 AQMP contemplated that implementation of 2022 AQMP control measures would result in potential NO_x emission reductions but with a corresponding increased demand for electricity if combustion sources in residential and commercial settings were replaced with electrified equipment. The control measures were evaluated for NO_x emission reductions at the regional level using statewide data. Due to a variety of factors such as the number of pieces of equipment, the size of the equipment, and the type of the operations, etc., it was difficult to quantify all potential electricity demand impacts. Nonetheless, for the equipment which has electricity use data available, electricity demand impacts were quantified but these estimates only provide a partial quantification of the overall potential electricity demand impacts from electrified equipment used in residential and commercial settings; see Table A-3. It was concluded that as more electric residential and commercial equipment is deployed, the demand for electricity would increase, while the demand for natural gas and its corresponding emissions would decrease, resulting in an overall net reduction in combustion emissions from residential and commercial equipment.

In addition to the increased electricity demand from electrification of residential and commercial equipment, the Final Program EIR for the 2022 AQMP also evaluated increased electricity demand from large industrial combustion equipment including hydrogen production, concluding that it would result in potentially significant air quality impacts, and mobile source conversion, concluding that it would result in less than significant air quality impacts.

The South Coast AQMD air quality significance thresholds for mass daily emissions of criteria pollutants are in units of pounds per day⁶⁵. The 2022 AQMP quantified NO_x reductions in tons per day (2,000 pounds = 1 ton). The 2022 AQMP was designed to attain the 8-hour ozone standard by reducing NO_x and to a lesser degree VOC emissions. Other emissions of criteria pollutants (i.e., CO, SO_x, PM₁₀, and PM_{2.5}) were also expected to be reduced. While most of the activities associated with the 2022 AQMP control measures were individually projected to have air quality impacts that were less than significant, activities associated with implementation of some individual control measures (i.e., increased electricity demand for large combustion equipment including hydrogen production) could result in potentially significant impacts. The precise magnitude of those emissions increases is dependent on the type and size of projects designed to comply with the control measures. Nonetheless, when the effects of all of the proposed control measures were considered together, a net NO_x emission reduction of 124 tons per day was expected, which was an order of magnitude greater than any of the adverse air quality impacts from some of the individual control measures such that the 2022 AQMP was expected to result in an air quality benefit. Thus, operational activities resulting from implementation of control measures in the 2022 AQMP were expected to generate less than significant criteria pollutant air quality impacts. Since no significant air quality impacts relating to operational activities were identified, no mitigation measures were necessary or required.

Impact to Greenhouse Gas (GHG) Emissions

The Final Program EIR for the 2022 AQMP contemplated implementation of Control Measure C-CMB-01 to involve construction activities which may emit GHGs. The physical changes are only attributed to implementation of Control Measure C-CMB-01 if equipment is replaced earlier than the end of unit age. For PAR 1146.2, because replacement of existing water heating equipment is expected occur at the end of unit age such that operators will remove the existing equipment and install a new water heating system regardless of the proposed amended rule, and because upgrades to electrical panels and other building components to enable the increased use of zero-emission equipment are not expected to require trenching or other construction requiring soil movement, implementation of PAR 1146.2 is not expected to cause construction GHG impacts.

Operational GHG emission increases are projected from energy demand increases to power zero-emission technologies. As mentioned in the Energy section, the Final Program EIR for the 2022 AQMP estimated that, compared to the 2018 baseline for electricity demand, implementation of the 2022 AQMP control measures is expected to increase electricity use by 13,429 GWh, approximately an 11 percent increase, by 2037 which will produce approximately 2.76 million metric tons (MMT) of GHG emissions.⁶⁶ The electricity needed to power zero-emission

⁶⁵ South Coast AQMD, South Coast AQMD Air Quality Significance Thresholds, <https://www.aqmd.gov/docs/default-source/ceqa/handbook/south-coast-aqmd-air-quality-significance-thresholds.pdf>

⁶⁶ 2020 eGRID data of 453 lb/MWh for SCE, U.S. EPA, 2022, <https://epa.gov/egrid/download-data>.

equipment, such as zero-emission water heaters, is expected to be provided by public utility companies. Most existing power generating facilities are subject to Assembly Bill 32 and will be required to reduce their GHG emissions. Moreover, any future power generating stations that may be built in response to meeting the future electricity demand would be subject to stringent emission control requirements, including those for GHG emissions. It is important to note that the 2022 AQMP also accelerates the penetration of zero- and near-zero-emission vehicles, and a reduction in the use of petroleum-based fuels will reduce criteria pollutants, toxics, and GHG emissions which will concurrently offset the projected increases in criteria pollutants, toxics, and GHG emissions from the use of more electricity. Converting gasoline- and diesel-fired sources to electrified equipment reliant on electricity that is primarily generated by natural gas and renewable sources is expected to result in an overall decrease of GHG emissions. Therefore, after taking into consideration the short-term increases in GHG emissions which will be offset by substantial reductions of GHG emissions from the decreased use of gasoline and diesel fuels combined with the overarching goal of transitioning to electricity sourced with 100 percent renewables by 2045 as required by Senate Bill 100 (SB 100, De León) the additional electricity that may be needed to implement the 2022 AQMP control measures has been determined to generate less than significant GHG emission impacts. Since no significant GHG impacts were identified, no mitigation measures were necessary or required.

In summary, relative to cumulative impacts, the Final Program EIR for the 2022 AQMP concluded that implementation of the 2022 AQMP, when combined with past, present, and reasonably foreseeable activities, would contribute to impacts to air quality during construction, but would not contribute to cumulatively considerable impacts to air quality during operation or GHG emissions.

However, since implementation of Control Measure C-CMB-01 of PAR 1146.2 is expected to have no air quality impacts during construction and GHG emissions, and a net benefit to air quality during operation, there are no new impacts which would change the previous conclusions of the Final Program EIR for the 2022 AQMP regarding cumulatively considerable impacts to air quality. Further, no new mitigation measures would be required. Therefore, the cumulative impacts to air quality would remain significant and unavoidable.

ENVIRONMENTAL TOPIC AREAS WITH NO IMPACTS

The 2022 AQMP was designed to reduce emissions from existing emission sources and promote the use of the cleanest technology available. The 2022 AQMP control measures focused on maximizing the implementation of existing zero-emission and low NO_x technologies, recognizing that new zero-emission and ultra-low NO_x technologies may still need to be invented or made commercially available to achieve the necessary reductions required to attain the 70 ppb ozone standard. The 2022 AQMP would accelerate the replacement of high-emitting mobile sources with low NO_x and zero-emission mobile sources; encourage the use of lower-emitting alternative fuels; affect stationary sources at existing commercial/industrial facilities and residential developments; develop incentives to remove/replace higher emitting equipment; establish greater control of industrial stationary sources; control indirect sources of emissions; improve energy efficiency; improve emission leak detection and maintenance procedures; and establish educational and outreach programs. The analysis provided in the Final Program EIR for 2022 AQMP concluded that implementation of Control Measure C-CMB-01 would have no impacts to the following

environmental topic areas: aesthetics, agriculture and forestry resources, biological resources, cultural and tribal cultural resources, geology and soils, hydrology and water quality, hazards and hazardous materials, land use and planning, mineral resources, noise, solid and hazardous waste, population and housing, public services, recreation, transportation, and wildfire. Since no impacts were identified, no mitigation measures are necessary or required for these environmental topic areas. Since PAR 1146.2 implements Control Measure C-CMB-01 without adding new or modifying the previously analyzed impacts for each environmental topic area, the overall conclusions of no impacts for these environmental topic areas in the Final Program EIR for the 2022 AQMP will remain unchanged if PAR 1146.2 is implemented.

The following summarizes the conclusions of no impacts in the Final Program EIR for the 2022 AQMP for each of these environmental topic areas.

Aesthetics: The majority of control measures implemented within South Coast AQMD's jurisdiction would typically affect industrial, institutional, or commercial facilities located in appropriately zoned areas (e.g., industrial and commercial areas) that are not usually associated with scenic resources. Further, modifications would typically occur inside buildings, within the confines of the affected facilities, or because of the nature of the business (e.g., commercial or industrial), can easily blend in with the facilities with little or no noticeable effect on adjacent areas. In addition, the 2022 AQMP contained control measures which focus on certain residential sources of air pollution (e.g., water heaters), and any modifications needed would occur inside buildings or in the case of energy efficiency improvements such as installing solar, on the roofs of residential buildings. Also improved air quality would provide benefits to scenic vistas and resources throughout South Coast AQMD's jurisdiction. Implementation of the 2022 AQMP control measures, such as Control Measure C-CMB-01, was not expected to create additional demand for new lighting or exposed combustion sources (e.g., flares) that could create glare, adversely affecting day or nighttime views in any areas. Facilities affected by the 2022 AQMP control measures typically make modifications to light sources within property borders, so any new light sources would typically be inside a building or not noticeable because of the presence of existing outdoor light sources. Based on these considerations, no significant aesthetic impacts were expected due to the implementation of the 2022 AQMP.

Agriculture and Forestry Resources: Implementation of 2022 AQMP control measures, including C-CMB-01, was not expected to generate any new construction of buildings or other structures that would require conversion of farmland to non-agricultural use, conflict with zoning for agricultural uses, or a Williamson Act contract. Further, 2022 AQMP control measures would typically affect existing facilities that are located in appropriately zoned areas. Any new facilities that may be affected by 2022 AQMP control measures would be constructed and operated for reasons other than complying with the control measures. Improvements would continue to be subject to project-level review, including review of agricultural impacts under CEQA. Therefore, implementation of the 2022 AQMP would not affect Prime Farmland, Unique Farmland, or Farmland of Statewide Importance, or conflict with a Williamson Act contract, if implemented. Physical changes associated with the 2022 AQMP were expected to occur at previously developed sites and would not warrant construction in undeveloped areas where agricultural and forest resources are more likely to exist. The 2022 AQMP control measures, including control measures related to mobile sources, would have no direct or indirect effects on agricultural or forest land resources because their focus is on achieving emission reductions by increasing the penetration of

zero and low NO_x technologies into market. The 2022 AQMP could provide benefits to agricultural and forest land resources by improving air quality in the region, thus reducing the adverse oxidation impacts of ozone on plants and animals.

Biological Resources: Implementation of the 2022 AQMP control measures, including C-CMB-01, was not expected to result in habitat modification, adversely affect any riparian habitat, or interfere with the movement of any native resident or migratory fish or wildlife species. Facilities affected by the 2022 AQMP control measures have already been disturbed and typically do not contain open space, water features, or natural vegetation. Sites might contain landscaping that consists of ornamental trees, vegetation, and turf. The sites of the affected facilities that would be subject to the control measures were not expected to support riparian habitat, federally protected wetlands, or migratory corridors because they are existing, developed, and established industrial and commercial facilities. Additionally, special status plants, animals, or natural communities identified in local or regional plans, policies, or regulations, or by the California Department of Fish and Wildlife or U.S. Fish and Wildlife Service were not expected to be found on or in close proximity to the affected facilities. Construction projects that impact affected species were not reasonably foreseeable as part of implementation of the 2022 AQMP. Any new development potentially affecting biological resources would not be as a result of the 2022 AQMP control measures and approval of those projects, including evaluation of their environmental impacts, would occur regardless of the 2022 AQMP and would be subject to project-level CEQA review. Based upon these considerations, significant adverse biological resources were not expected from implementing the 2022 AQMP.

Cultural and Tribal Cultural Resources: Commercial and industrial areas are generally not located in historic districts, and implementation of the 2022 AQMP control measures, including C-CMB-01, was not expected to cause a substantial adverse change in the significance of a historical resource. The South Coast AQMD also provided a formal notice of the 2022 AQMP to all California Native American Tribes (Tribes) that requested to be on the Native American Heritage Commission's (NAHC) notification list per Public Resources Code Section 21080.3.1(b)(1). The NAHC notification list provides a 30-day period during which a Tribe may respond to the formal notice, in writing, requesting consultation on the proposed project. No Tribes requested consultation during the 30-day comment period. The provisions of CEQA, Public Resources Code Section 21080.3.1 et seq. (also known as AB 52), require meaningful consultation with California Native American Tribes on potential impacts to tribal cultural resources, as defined in Public Resources Code Section 21074. Tribal cultural resources are sites, features, places, cultural landscapes, sacred places, and objects with cultural value to a California Native American tribe that are either eligible or listed in the California Register of Historical Resources or local register of historical resources. As part of the AB 52 process, Native American tribes must submit a written request to the relevant lead agency if it wishes to be notified of projects that require CEQA public noticing and are within its traditionally and culturally affiliated geographical area. Construction resulting from implementation of the proposed control measures would need to obtain city or county planning department approvals prior to commencement of any construction activities, and would be subject to project-level review, including separate tribal consultation pursuant to AB 52, as applicable, to address site-specific requests identified by the tribes. Therefore, impacts to tribal cultural resources were considered to be less than significant, and the 2022 AQMP was not expected to cause any impacts to significant historic cultural resources.

Geology and Soils: The 2022 AQMP control measures, including C-CMB-01, would not directly or indirectly expose people or structures to earthquake faults, seismic shaking, seismic-related ground failure including liquefaction, lateral spreading, landslides, mudslides, or substantial soil erosion. Most facilities affected by 2022 AQMP control measures would be located on previously disturbed industrial and commercial sites where there is little likelihood of identifiable artifacts. It is possible, however, that cultural or archaeological resources or human remains may nevertheless be discovered. New installations of air pollution control equipment or infrastructure for zero-emission and low-NOx equipment are unlikely to require substantial soil excavation and would be located on already disturbed and developed industrial land uses. Therefore, no significant impact would occur. Further, projects implemented as a result of the 2022 AQMP would be subject to project-level review, including review of both geological and paleontological impacts under CEQA, as applicable. Therefore, implementation of the 2022 AQMP was not expected to directly or indirectly destroy a unique paleontological resource or site or unique geological feature or result in other significant adverse geology or soils impacts.

Hydrology and Water Quality: No potential impacts were expected as a result of implementing Control Measure C-CMB-01 of the 2022 AQMP. Implementation of the Control Measure C-CMB-01 would not involve the following activities which were concluded in the Final Program EIR for the 2022 AQMP to collectively cause potentially significant hydrology and water quality impacts: 1) potential increase in water demand; 2) potential increase in wastewater discharge and related water quality impacts; 3) water quality impacts associated with increased use of and accidental releases of alternative fuels; 4) water quality impacts associated with accidental releases of ammonia from operation of SCR technology; 5) water quality impacts associated with accidental releases from battery disposal and processing including acid spills; and, 6) water quality impacts associated the use and clean-up of reformulated products. Therefore, the implementation of Control Measure C-CMB-01 was not expected to create significant impact on hydrology and water quality.

Hazards and Hazardous Materials: No potential impacts were expected as a result of implementing Control Measure C-CMB-01 of the 2022 AQMP. Implementation of the Control Measure C-CMB-01 would not involve with the following activities which were concluded in the Final Program EIR for the 2022 AQMP to collectively cause potentially significant hazardous and hazardous materials impacts: 1) the routine transport, storage, and use of ammonia in air pollution control equipment; 2) the production, storage, and use of alternative fuels including but not limited to natural gas and hydrogen to produce electricity and to fuel on- and off-road mobile sources; 3) disposal of batteries, fluids, and spent catalyst; 4) increased use of lower-VOC containing products reformulated with flammable materials; and 5) conducting chipping and grinding of wood and greenwaste in fire hazard area. Therefore, Control Measure C-CMB-01 was not expected to create significant impact on hazardous and hazardous materials.

Land Use and Planning: Since the 2022 AQMP does not require construction of major new land use developments in any areas within South Coast AQMD's jurisdiction, none of the control measures, including C-CMB-01, were expected to physically divide any established communities within South Coast AQMD's jurisdiction. Potential land use impacts associated with the 2022 AQMP could come from the construction of support systems (e.g., catenary overhead electrical lines or magnetic infrastructure related to operation of zero- and low-NOx transport systems). For purposes of evaluating potential land use impacts, the analysis assumed that no new rail or truck

traffic routes would be constructed, but rather that existing truck and rail routes and corridors would be modified. The truck and rail corridors likely to be involved are primarily associated with rail yards and intermodal facilities in industrial zones within the Southern California area. Since only existing transportation routes would likely be modified (e.g., electric lines installed) and no new transportation routes were anticipated, no land use conflicts, or inconsistencies with any general plan, specific plan, local coastal program, or zoning ordinance were expected. Activities that result from implementing the various 2022 AQMP control measures would be subject to project-level review that would assess consistency with adopted land use regulations, including review of impacts to land use and planning under CEQA, as applicable. Any proposed modification to an existing rail or truck traffic route/corridor would require a separate CEQA evaluation. No significant land use impacts were identified because any activities undertaken to implement the 2022 AQMP control measures would be expected to comply with, and not interfere with, applicable land use plans, policies, or regulations of an agency with jurisdiction over the project, including, but not limited to the general plans, specific plans, local coastal programs or zoning ordinances.

Mineral Resources: There were no provisions in the 2022 AQMP that would result in the loss of availability of a known mineral resource of value to the region and the residents of the state, or of a locally-important mineral resource recovery site delineated in a local general plan, specific plan, or other land use plan. The 2022 AQMP provides incentives for the penetration of low-NOx and zero-emission technologies into the market which are not expected to result in an increase in the use of mineral resources. The 2022 AQMP was not expected to have any significant effects on the use of important minerals. Therefore, no new demand for mineral resources was expected to occur and no significant adverse mineral resources impacts from implementing the proposed project were anticipated.

Noise: Implementation of a project would be considered to have significant adverse noise impacts if any of the following conditions occur: 1) construction noise levels exceed the local noise ordinances or, if the noise threshold is currently exceeded, project noise sources increase ambient noise levels by more than three decibels (dBA) at the site boundary. Construction noise levels will be considered significant if they exceed federal Occupational Safety and Health Administration (OSHA) noise standards for workers; and 2) the proposed project operational noise levels exceed any of the local noise ordinances at the site boundary or, if the noise threshold is currently exceeded, project noise sources increase ambient noise levels by more than three dBA at the site boundary. The Final Program EIR for the 2022 AQMP concluded that implementation of 2022 AQMP control measures could result in significant noise and vibration impacts from construction activities, so mitigation measures were proposed. Potential operational noise impacts were concluded to be less than significant so that no mitigation measures were required. Control Measure C-CMB-01 of the 2022 AQMP was contemplated to have potential noise impacts during construction, and this would be the result if equipment was replaced prior to the end of its unit age. PAR 1146.2 schedules equipment replacement at the end of the existing equipment's unit age. Construction associated with demolition or removal of existing building components or structures, and water heating systems; and installation of new water heating systems, would occur regardless of PAR 1146.2 and therefore are not results of implementing the proposed amended rule. Electrical panel upgrades resulting from implementation of PAR 1146.2 are not expected to require trenching or other construction such that significant noise would be generated. Therefore, implementation of PAR 1146.2 is not expected to have an effect on noise.

Population and Housing The 2022 AQMP control measures were not anticipated to generate any significant effects, either direct or indirect, on the population or population distribution of people living in the South Coast AQMD's jurisdiction as no additional workers were anticipated to be required in order to implement any of the 2022 AQMP control measures. Consistent with past experience, it was expected that the existing labor pool within the southern California area would accommodate the labor requirements for any modifications requiring construction at affected facilities. Additionally, the 2022 AQMP control measures, including C-CMB-01, contain no provisions that would cause displacement of substantial numbers of people or housing necessitating construction of replacement housing elsewhere. Accordingly, population and housing impacts were not expected from the implementation of the 2022 AQMP.

Public Services: Fire protection and emergency medical services are provided to affected facilities and residential developments by local county and city fire departments. All activities undertaken as a result of implementing the 2022 AQMP control measures, including C-CMB-01, would be required to comply with fire-related safety features in accordance with the applicable provisions of the adopted California Fire Code, any county or city ordinances, and standards regarding fire prevention and suppression measures related to water improvement plans, fire hydrants, fire access, and water availability. Based on the preceding discussion, implementation of the 2022 AQMP control measures would not adversely affect the ability of local fire protection to provide adequate service and impacts would be less than significant. Implementation of the 2022 AQMP control measures would not result in an increase in calls for police protection. Implementation of the 2022 AQMP control measures occur at existing facilities or promote transition to cleaner emitting equipment at new developments but would not facilitate the construction of new development. At existing industrial facilities, on-site security is typical and would be expected to continue with the same demand for police department support as is currently needed. Furthermore, implementation of the 2022 AQMP control measures would not induce population growth either directly or indirectly. Therefore, with no increase in local population, there would be no additional demand for new or expanded schools, parks, and libraries and no other adverse population or housing impacts were expected.

Recreation: Demand for parks and recreational facilities in an area is usually determined by the area's population. Per Population and Housing section, the implementation of the 2022 AQMP control measures does not include the development of new homes, which would lead to an increase in population and thereby, the need for additional park and recreation facilities. Therefore, the implementation of the 2022 AQMP control measures, including C-CMB-01, would not increase the use of existing neighborhood and regional parks or other recreational facilities, nor would it require construction of new or expanded parks or recreational facilities. No impacts to park and recreational facilities would occur and no mitigation measures were necessary.

Solid and Hazardous Waste: Implementation of a project would be considered to have significant solid and hazardous waste impacts if the generation and disposal of hazardous and non-hazardous waste exceeds the capacity of designated landfills. The Final Program EIR for the 2022 AQMP concluded that implementation of 2022 AQMP control measures could result in significant solid and hazardous waste impacts, so mitigation measures were proposed. Control Measure C-CMB-01 of the 2022 AQMP was contemplated to have potential solid and hazardous waste impacts during construction activities and from disposal of old equipment, and this would be the result if equipment was replaced prior to the end of its unit age. PAR 1146.2 schedules equipment

replacement at the end of the existing equipment's unit age. Construction associated with demolition or removal of existing building components or structures, and water heating systems would occur regardless of PAR 1146.2 and therefore are not results of implementing the proposed amended rule. Electrical panel upgrades resulting from implementation of PAR 1146.2 are not expected to require trenching or other construction such that significant waste would be generated. Therefore, implementation of PAR 1146.2 is not expected to have an effect on solid and hazardous waste.

Transportation: Implementation of the 2022 AQMP control measures, including C-CMB-01, was not expected to substantially alter vehicle mileage or transportation routes. The 2022 AQMP builds upon transportation and related Transportation Control Measure (TCMs) developed by Southern California Association of Governments (SCAG) and included in the SCAG Regional Transportation Plan/Sustainable Communities Strategy (RTP/SCS). Therefore, the 2022 AQMP control measures would not conflict with a program plan, ordinance, or policy addressing the circulation system, including transit, roadway, bicycle, and pedestrian facilities. The 2022 AQMP revised the previous motor vehicle emissions budgets with new emission calculations using the latest motor vehicle emission factors and planning assumptions. The U.S. EPA's Transportation Conformity Rule requires that transportation plans and projects must not exceed SIP motor vehicle emission budgets for attaining and maintaining health-based air quality standards or a conformity lapse would occur (preventing further funding of transportation projects). By avoiding a conformity lapse, the region would continue to receive federal funding for future transportation projects, which would generally improve traffic flow. Implementation of the 2022 AQMP control measures has the potential to result in an increase in transportation related to construction of new or modified air pollution control equipment. Construction trips and vehicle miles traveled (VMT) are associated with contractors and vendors delivering and installing equipment at affected facilities. Construction activity impacts are temporary in nature and will vary depending on the number and location of facilities, and the size of the construction workforce needed. The CARB Technical Advisory on Evaluating Transportation Impacts in CEQA to comply with CEQA Guidelines Section 15064.3 focuses on permanent, new employee VMT. [California Office of Planning and Research, 2018]. Because of the temporary nature of construction activities, any increase in VMT related to construction activities would occur on a short-term basis at each location. In general, temporary construction-related increases in VMT are not considered to be a transportation impact or inconsistent with the requirements in CEQA Guidelines Section 15064.3, as they do not have a permanent impact on regional VMT. Additionally, discretionary projects at affected facilities could be subject to project-level review under CEQA. Therefore, temporary effects of construction-related vehicles would not conflict with the state's GHG reduction and associated VMT goals for the transportation sector. CEQA Guidelines Section 15064.3(a) clarifies that the primary consideration in evaluating a project's transportation impacts for CEQA purposes is the amount and distance that a project might cause people to drive. This captures two measures of transportation impacts: number of automobile trips generated and VMT. Additional permanent employees were not expected to be required to operate equipment that may require additional air pollution control equipment, due to implementation of the 2022 AQMP. As discussed in the Population and Housing paragraph, implementation of the 2022 AQMP was not expected to generate additional employee or population increases. Therefore, no increase in vehicle trips or VMT was expected. Therefore, less than significant impacts from the implementation of the 2022 AQMP control measures were expected to occur.

Wildfire: Activities that result from implementation of the 2022 AQMP control measures, including C-CMB-01, would not block or otherwise interfere with the use of evacuation routes; nor would they interfere with operations of emergency response agencies or with coordination and cooperation between such agencies. Therefore, there would be no impacts on emergency activities. For the 2022 AQMP control measures that affect residential land uses, any modifications needed would occur inside the buildings or in the case of energy efficiency improvements would not be expected to create any greater risk of wildland fires than the existing residential developments themselves. Moreover, the proposed residential control measures may involve replacing gas-fired water heaters and other combustion sources with electric devices, which would reduce the use of fuel and the potential to cause wildland fires.

In summary, relative to cumulative impacts, the Final Program EIR for the 2022 AQMP concluded that implementation of the 2022 AQMP, when combined with past, present, and reasonably foreseeable activities, would not contribute to cumulative considerable impacts to the following environmental topic areas: aesthetics, agriculture and forestry resources, biological resources, cultural and tribal cultural resources, geology and soils, hydrology and water quality, hazards and hazardous material, land use and planning, mineral resources, noise, population and housing, public services, recreation, solid and hazardous waste, transportation, and wildfire.

Since implementation of Control Measure C-CMB-01 of PAR 1146.2 is expected to have no impact on any of the above environmental topic areas, there are no new impacts which would change the previous conclusions of the Final Program EIR for the 2022 AQMP regarding cumulatively considerable impacts. Further, no new mitigation measures would be required. Therefore, there are no cumulative impacts to the environmental topic areas of aesthetics, agriculture and forestry resources, biological resources, cultural and tribal cultural resources, geology and soils, hydrology and water quality, hazards and hazardous material, land use and planning, mineral resources, noise, population and housing, public services, recreation, solid and hazardous waste, transportation, and wildfire.

CONCLUSION

PAR 1146.2 implements Control Measure C-CMB-01 that was previously adopted in the 2022 AQMP. There are no new or modified physical changes that would result from implementing PAR 1146.2 which were not previously analyzed in the Final Program EIR for the 2022 AQMP specific to Control Measure C-CMB-01. Further, implementation of Control Measure C-CMB-01 contemplated additional physical changes which would not be expected to occur if PAR 1146.2 is implemented because equipment replacements will occur at the end of the existing equipment's unit age. Construction associated with demolition or removal of existing building components or structures and water heating systems, and the installation of new water heating systems would occur regardless of PAR 1146.2 and therefore, these activities are not the consequence of implementing PAR 1146.2. Electrical panel upgrades resulting from implementation of PAR 1146.2 are not expected to require trenching or other construction requiring soil movement.

Control Measure C-CMB-01 of the 2022 AQMP was previously analyzed in the Final Program EIR for the 2022 AQMP, and implementation of PAR 1146.2 is not expected to result in new or modified physical changes or impacts that were not previously analyzed in the Final Program EIR for the 2022 AQMP.

The Final Program EIR for the 2022 AQMP concluded potentially significant impacts to the environmental topic areas of air quality and greenhouse gas emissions, energy, hazards and hazardous materials, hydrology and water quality, noise, and solid and hazardous waste. However, the Final Program EIR for the 2022 AQMP concluded that implementation of Control Measure C-CMB-01 would have no impacts to the environmental topics of hazards and hazardous materials, and hydrology and water quality. Further, because PAR 1146.2 contemplates the replacement of existing equipment at the end of its unit age, plus new installations of water heating systems would be installed regardless of the proposed amended rule, implementation of PAR 1146.2 would have no impact to air quality during construction, noise, or solid and hazardous waste. The Final Program EIR for the 2022 AQMP concluded implementation of Control Measure C-CMB-01 would have potentially significant energy impacts due to increased electricity use and increased natural gas use to produce electricity, and less than significant impact to operational air quality and greenhouse gas emissions due to use of electricity and combustion of natural gas, and these impacts are the same as what would occur if PAR 1146.2 is implemented.

For environmental topic areas which were concluded in the Final EIR for the 2022 AQMP to have potentially significant impacts, mitigation measures were adopted. Nonetheless, no environmental topic area identified as having a potentially significant impact in the Final Program EIR for the 2022 AQMP was concluded to be capable of being mitigated to less than significant levels. When combined with the Connect SoCal Plan, the SIP strategies, state policies, and other past, present, and reasonably foreseeable activities, implementation of the 2022 AQMP would result in significant environmental impacts. No additional feasible mitigation measures to reduce the significant cumulative impacts were identified, and cumulative impacts to the environmental topic areas of air quality and greenhouse gas emissions, energy, hazards and hazardous materials, hydrology and water quality, noise, and solid and hazardous waste remained significant and unavoidable.

Therefore, the environmental impacts associated with implementing PAR 1146.2 are within the scope of what was previously analyzed in the Final Program EIR for the 2022 AQMP for Control Measure C-CMB-01. Thus, no new Initial Study would need to be prepared leading to either an EIR or a Negative Declaration pursuant to CEQA Guidelines Section 15168(c)(2). PAR 1146.2 does not introduce new information which will cause new significant effects or substantially worsen or make more severe significant effects that were previously analyzed in the Final Program EIR for the 2022 AQMP. There is no change to the mitigation measures or alternatives previously considered in the Final Program EIR for the 2022 AQMP. Thus, in accordance with CEQA Guidelines Section 15168(c)(2), a subsequent EIR would not be required pursuant to CEQA Guidelines Section 15162.

Based on the preceding analysis, pursuant to CEQA Guidelines Section 15168(c)(2), PAR 1146.2 is considered a later activity within the scope of the 2022 AQMP which was analyzed in the Final Program EIR for the 2022 AQMP. The mitigation measures developed in the Final Program EIR for the 2022 AQMP for the previously adopted Control Measure C-CMB-01 in the 2022 AQMP upon which PAR 1146.2 relies are also applicable to the implementation of PAR 1146.2 and will remain in effect. [CEQA Guidelines Section 15168(c)(3)].

Therefore, PAR 1146.2 is considered a later activity within the scope of the Final Program EIR for the 2022 AQMP and the Final Program EIR for the 2022 AQMP adequately describes the later activity for the purposes of CEQA such that no new environmental document will be required.

APPENDIX B: RESPONSES TO COMMENTS

PUBLIC WORKSHOP COMMENTS

Staff held the Public Workshop on February 7, 2024, to provide a summary of PAR 1146.2. The following is a summary of the comments received on PAR 1146.2 and staff responses.

Comment PW-1: Robert Benz (Benz Air Engineering, Co. Inc.)

Staff should evaluate lifecycle emissions from electric generation.

Response to Comment PW-1:

Staff recognizes that there are externalities for both electric and natural gas production and distribution. Staff also recognizes the need for regulation of emissions from electricity generation. South Coast AQMD Rule 1135 – Emissions of Oxides of Nitrogen from Electricity Generating Facilities, is a rule that aims to lower emissions from electricity generation. Regarding the natural gas system, natural gas leaks into the atmosphere from natural gas wells, storage tanks, pipelines, and processing plants. In 2020, methane emissions from natural gas and petroleum systems and from abandoned oil and natural gas wells were the source of approximately 33 percent of U.S. methane emissions and approximately four percent of U.S. greenhouse gas emissions. In the South Coast AQMD region, there have been examples of large leaks such as Aliso Canyon, where 109,000 metric tons of methane emissions were released between October 2015 and February 2016. For this rulemaking, staff did not conduct lifecycle analyses related to the BARCT assessment for either the electricity or natural gas systems.

Comment PW-2: Joe Boros (Rheem Manufacturing Company)

Retrofitting gas units with heat pumps requires higher costs and more equipment space.

Response to Comment PW-2:

Staff gathered cost data for various types of units for the cost-effectiveness analysis described in Chapter 2 of this report. Heat pumps are the primary zero-emission technology evaluated. The analysis accounted for higher equipment and installation costs, operational cost of switching from gas to electricity, and electrical upgrade cost for some cases. Although the analysis determined that it is cost-effective for most of the equipment categories to implement zero-emission, staff understands the challenge of higher upfront cost. Staff is in the process of developing a rebate program to help lower the cost for some consumers and centralizing information for incentive and financing opportunities offered by other agencies and organizations. Further, as zero-emission technologies become more mature and more widely adopted in the market, there will be less cost impact.

Regarding the required space for zero-emission equipment, staff conducted numerous site visits for heat pump installations in commercial buildings such as multifamily buildings, hotels, and groceries stores, and discussed case studies with stakeholders and organizations that incentivize the installation of heat pumps. While some heat pumps may require more space for operation than natural gas-fired units, the heat pump installations that staff observed were capable of fitting in the existing room or area. Staff conducted site visits to various locations to consider the spacing challenge and found feasibility for all sites visited. Staff recognizes that some stakeholder's case studies failed to consider the high energy

efficiency of heat pumps, and thus have oversized the heat pump replacement, overestimating the number or the capacity of heat pumps and storage tanks, thus taking up more space. Nevertheless, staff has proposed to provide an extension of up to ~~six~~ 18 months for an owner or operator of a unit to comply with the zero-emission standards if the installation is delayed because construction is required to expand the space designed to house the unit and associated equipment necessary for operating the unit.

Existing buildings may have more challenges than new buildings to replace gas-fired units and thus may have potentially increased costs. To address this potential increased cost, staff included a 20 percent increase to the cost of zero-emission units, which could be an underestimate for some and overestimate for others. In addition, staff included alternative compliance options to address any potential utility upgrade and emergency replacement concerns and has provided later implementation dates to give more time for units in existing buildings to be replaced.

Staff will continue to monitor all the challenges for zero-emission implementation and is committed to conduct a technology check-in and report the findings to the Stationary Source Committee by ~~January 1, 2028~~ June 1, 2027.

Comment PW-3: Kevin Pirotin (Navien, Inc.)

There should be provisions for emergency replacement.

Response to Comment PW-3:

Staff understands the concern and added paragraph (i)(4) to provide an alternative compliance option for emergency replacement when an electrical upgrade for more power supply capacity is required to comply with zero-emission limits. This allows the use of a temporary unit that complies with Table 1 emission limits (20 ppmv NOx/400 ppmv CO) for up to six months. When the owner or operator of a unit subject to alternative compliance options in paragraph (i)(1) for utility upgrades, paragraph (i)(6) for property under lease, or paragraph (i)(7) for construction upgrade and the unit is non-operational, the owner or operator can use a temporary unit that complies with Table 1 emission limits (20 ppmv NOx/400 ppmv CO) during the approved extension.

Comment PW-4: Kevin Pirotin (Navien, Inc.)

Suggested to align proposed compliance dates with Title 24 Building Code effective dates.

Response to Comment PW-4:

Staff revised the compliance dates and extended both Phase I and Phase II compliance dates for new buildings by one year. The proposed Phase I compliance date for new buildings is January 1, 2026, aligning with the expected effective date for the next updated Title 24 Building Code.

Comment PW-5: James Phillips (Rheem Manufacturing Company)

Suggested to use 180 degrees Fahrenheit instead of 190 degrees Fahrenheit for the high temperature unit definition to align with the Code of Federal Regulations definition

Response to Comment PW-5:

Staff revised the high temperature unit definition and changed 190 degrees Fahrenheit to 180 degrees Fahrenheit, aligning the temperature threshold with the Code of Federal Regulations definition for “residential-duty commercial water heater” for outlet water temperature.

Comment PW-6: Kevin Pirotin (Navien, Inc.)

Suggested to align the instantaneous water heater compliance date with PAR 1121 implementation date.

Response to Comment PW-6:

Staff is currently working on the Proposed Amended Rule 1121 (PAR 1121); however, implementation deadlines have not been established. PAR 1121 regulates most residential water heaters, but instantaneous water heaters, which are mostly installed in residential structures, are subject to Rule 1146.2. Building readiness is being evaluated for both PAR 1146.2 and PAR 1121. Staff will consider aligning compliance dates but will determine if further analysis on technologies and other factors for PAR 1121 will require different implementation schedules.

Comment PW-7: Joe Boros (Rheem Manufacturing Company)

Expressed concern about removing the 9,000 therms per year low-use exemption.

Response to Comment PW-7:

The existing rule exemption is intended for Type 2 units manufactured prior to January 1, 2000, with NO_x emissions higher than 30 ppm NO_x. The 9,000 therms per year low-use threshold is about 50 percent of typical annual fuel use for a medium size Type 2 unit, which is no longer justifiable as low-use. Staff has proposed to phase out this exemption when zero-emission implementation starts on January 1, 2031 or January 1, 2033 for Type 2 high temperature units. PAR 1146.2 establishes a new low-use exemption from Table 2 zero-emission requirements in paragraph (k)(3). Annual use of 3,000 therms is about 16 percent of normal fuel use for a 1 MMBtu/hr unit and annual use of 2,000 therms is about 27 percent of normal fuel use for a 400 kBtu/hr unit. The provisions of paragraphs (d)(2) and (d)(3) and subparagraph (d)(5)(B) shall not apply to the following existing units installed prior to the date of rule adoption that meet Table 1 emission limits: units with a rated heat input capacity greater than 1 MMBtu/hr, but less than or equal to 2 MMBtu/hr that are demonstrated to use less than 3,000 therms during every calendar year for; or units with a rated heat input capacity greater than 400 kBtu/hr, but less than or equal to 1 MMBtu/hr that demonstrate to use less than 2,000 therms during every calendar year.

Comment PW-8: Adrian Martinez (Earthjustice)

Suggested not to have any delay on adopting zero-emission requirements.

Response to Comment PW-8:

Staff recognizes the need to pursue emission reduction with an earlier timeframe to address the air quality needs of the South Coast AQMD. PAR 1146.2 is currently scheduled to be presented to the Governing Board in ~~the second quarter of~~ June 2024 for consideration.

PUBLIC CONSULTATION COMMENTS

Staff held the Public Consultation on February 23, 2024, to provide a summary of PAR 1146.2. The following is a summary of the comments received on PAR 1146.2 and staff responses.

Comment PC-1: Steve Mertz (DB Sales & Service)

Heat pump operational cost is high.

Response to Comment PC-1:

Staff gathered cost data for various types of units for the cost-effectiveness analysis described in Chapter 2 of this report. Heat pumps are the primary zero-emission technology. The analysis has accounted for higher equipment and installation costs, operational cost of switching from gas to electricity, and electrical upgrade cost for some cases. Staff understands the challenge of higher costs and is in the process of developing a rebate program to lower the cost for some consumers and centralizing information on incentives and financial opportunities available from other agencies and organizations. Staff also expects the costs to decrease as more zero-emission technologies become available. Please see also Response to Comment PW-2 .

Comment PC-2: Robert Benz (Benz Air Engineering, Co. Inc.)

Staff should consider near-zero-emission units.

Response to Comment PC-2:

The 2022 AQMP's objective is to transition to zero-emission technologies wherever feasible and staff identified technically feasible zero-emission control options for each category of equipment subject to Rule 1146.2. The 2022 AQMP stated that near-zero-emission technology would be considered when zero-emission technologies were not technically feasible, which is not the case for PAR 1146.2.

Comment PC-3: Robert Benz (Benz Air Engineering, Co. Inc.)

Staff should evaluate life cycle emissions from electric generation.

Response to Comment PC-3:

Please see Response to Comment PW-1 which provides staff response to the same comment.

Comment PC-4: Kevin Pirotin (Navien, Inc.)

Suggested to align instantaneous water heater compliance date with PAR 1121 implementation date.

Response to Comment PC-4:

Please see Response to Comment PW-6 which provides staff response to the same comment.

Comment PC-5: William Pearce (The Boeing Company)

Suggested to increase all unit ages by five years.

Response to Comment PC-5:

In previous Rule 1146.2 rulemaking, unit age of 15 years was utilized for the analysis. Meetings and site visits with different manufacturers during the current rulemaking process indicated unit ages of under and over 25 years for gas-fired units. U.S. DOE estimates that with proper installation and maintenance, heat pump pool heaters can last 10 or more years. The BAAQMD staff report for Rules 9-4 and 9-6 indicated that water heaters were assumed to have an average lifespan of 13 years. For PAR 1146.2, staff utilized 15 years for Type 1 units that are not instantaneous water heaters or high temperature units and utilized 25 years for other categories to align more closely with other rulemakings while taking into consideration comments on longer unit ages.

Comment PC-6: Amanda Grey (University of California, Riverside)

For the alternative compliance option for multiple unit replacement, suggested to lower the threshold from five units to a number less than five units that are required to meet zero-emissions in the same calendar year.

Response to Comment PC-6:

The alternative compliance option for multiple unit replacement was initially proposed for cases where an owner or operator has five or more units that are required to meet zero-emission limits in the same calendar year. Similar provision have been included in other South Coast AQMD rules. However, staff has revised the proposal after the Public Workshop to have this provision applicable for cases where five or more units are required to meet zero-emission limits in two consecutive calendar years. The proposed provision allows three years extension for the implementation of five or more units, which means one or more units should be replaced each year. Staff believes the revised proposal is reasonable and have addressed the comment in an alternative way.

Comment PC-7: Sassan Rahimzadeh (Arya Cleaners)

Concern about dry cleaners' ability to upgrade gas-fired units to zero-emission units.

Response to Comment PC-7:

Staff has contacted the California Cleaners Association previously and is currently in contact for further discussion on any challenges. [Staff has conducted meetings and site visits with dry cleaners to understand the concern.](#) The dry cleaners' primary concern is the high upfront cost to install a new zero-emission unit. Staff is in the process developing a rebate program to help lower the cost for some consumers and centralizing information for incentive and financing opportunities offered by other agencies and organizations. As zero-emission technologies become more mature and more widely adopted in the market, there will be less cost impact. In addition, staff is projecting future utility savings based on projected natural gas and electricity prices. The cost to operate heat pumps is lower than most electric appliances because they are so energy efficient; over the lifetime of the unit, that initial cost increase could be recovered.

Staff proposed several alternative compliance options, a limited exemption for small businesses, and a longer compliance timeline, further detailed in Chapter 3, that dry cleaners would be able to utilize, including:

- Paragraph (i)(1) provides an alternative compliance option for when utility upgrades delay compliance with zero-emission limits. When the applicable utility company is unable to provide the necessary power which is beyond the owner or operator's reasonable control, the owner or operator can request an extension of up to ~~36~~60 months for compliance.
- Paragraph (i)(4) provides an alternative compliance option for emergency replacement when an owner or operator requires a short-term replacement due to sudden unit failure after the applicable Table 3 compliance date if an electrical upgrade is needed to operate a unit that complies with Table 2 emission limits. In this situation, the owner or operator may elect to install and operate a temporary unit that complies with Table 1 emission limits for up to six months.
- For a dry cleaner in a property under lease, paragraph (i)(6) provides another alternative compliance option that allows an extension of up to 24 months to comply with the Table 2 emission limits, if the installation is delayed beyond the reasonable control of the owner or operator of the unit.
- Paragraph (i)(7) provides an alternative compliance option that allows for an extension of up to 18 months from the applicable compliance date for when installation is delayed because construction is required to expand the space designed to house or relocate the unit, and associated equipment necessary for operating the unit, excluding units utilizing the alternative compliance options specified in paragraphs (i)(1), (i)(2), (i)(5), and (i)(6).
- There is also an exemption in paragraph (k)(5) that the provisions of paragraph (d)(3) regarding replacing existing units once they reach their defined unit age in the rule shall not apply to units installed in facilities that meet the Rule 102 definition of a small business. For small businesses, existing units can be operated until their natural replacement after the applicable Table 3 compliance date.
- Boilers operated by dry cleaners are categorized as high temperature units, for which PAR 1146.2 has proposed a later zero-emission implementation date (i.e., 2033 for existing buildings).

Staff will continue to monitor all the challenges for zero-emission implementation and will conduct a technology check-in and report the findings to the Stationary Source Committee by ~~January 1, 2028~~June 1, 2027.

Comment PC-8: Jed Holtzman (RMI)

Staff should reconsider the 3,000 therms per year low-use threshold which is not a de minimis value for annual fuel use of smaller units.

Response to Comment PC-8:

The existing rule allow for a low-use exemption for older Type 2 units with annual fuel use of 9,000 therms. Those units were manufactured prior to January 1, 2000, with NO_x emissions higher than 30 ppmv NO_x. PAR 1146.2 proposes to phase out the existing 9,000 therms exemption when zero-emission implementation starts and include a new low-use exemption as a transitional option. The new low-use exemption from Table 2 zero-emission requirements is for a Type 2-unit meeting Table 1 emission limits (i.e., 20 ppmv NO_x and 400 ppmv CO) with fuel use less than 3,000 therms per year. For context, annual use of 3,000 therms is about 16 percent of normal fuel use for a 1 MMBtu/hr unit and 40 percent of normal fuel use for a 400 kBtu/hr unit; 3,000 therms is about two hours of use per day, 960 lbs of NO_x per year, or 2.6 lbs of NO_x per day. Staff has further revised the low-use threshold for smaller units. For smaller units with heat input capacity rated between 400 kBtu/hr and 1 MMBtu/hr, staff is proposing a lower threshold such as 2,000 therms per year which is about 27 percent of normal fuel use for a 400 kBtu/hr unit.

Comment PC-9: Michael Corbett (Bradford White Corporation)

Opposed the labeling requirement.

Response to Comment PC-9:

Labeling requirements were previously proposed and removed. However, concerns were raised for how the zero-emission limits will be enforced when new buildings are required to have zero-emission units installed and existing buildings can have units with 20 ppmv NO_x limits installed. PAR 1146.2 is proposing a labeling requirement under the new subdivision (j) for the period between new building compliance date and existing building compliance date of an equipment category, and the extended period for tankless water heaters replacing existing tankless water heaters in mobile homes.

Labeling requirements are common for area source rules. For example, Rule 1111 has several labeling requirements. One of the requirements specified by subparagraph (e)(3)(B) of Rule 1111 requires manufacturers to display a labeling language for unit using an alternative compliance plan in lieu of meeting the 14 ng/J NO_x limit: “If installed in South Coast AQMD only: This furnace does not meet the South Coast AQMD Rule 1111 NO_x emission limit (14 ng/J), and thus is subject to a mitigation fee of up to \$450. This furnace is not eligible for the Clean Air Furnace Rebate Program: www.CleanAirFurnaceRebate.com.” Labeling requirements are important tools for enforcement, especially when some units distributed to the market can only be installed under certain conditions. Manufacturers may elect to send a sticker or label to distributors to be applied upon unit installation.

Comment PC-10: James Phillips (Rheem Manufacturing Company)

Units for multifamily structures should be exempted from retrofit requirement.

Response to Comment PC-10:

The retrofit requirement is intended for installations in industrial and commercial entities; therefore, units for residential structures are exempted from this requirement. Multifamily

structures are grouped with other commercial buildings (e.g., hotels and motels) by the CEC manual for the 2022 Building Code.⁶⁷ Although the PAR 1146.2 analysis determined that it is cost-effective for most of the equipment categories to implement zero-emission, staff understands the higher upfront cost is a concern. Staff is in the process developing a rebate program to help lower the cost for some consumers, including owners or operators of multifamily structures, and centralizing information for incentive and financing opportunities offered by other agencies and organizations. Further, as zero-emission technologies become more mature and more widely adopted in the market in the future, there will be less cost impact.

Comment PC-11: Adrian Martinez (Earthjustice)

Urged no further delay of the rule adoption and recommended allocating funding to support the early adoption of zero-emission units.

Response to Comment PC-11:

Please see Response to Comments and PW-8 which provide staff responses to the same comment.

⁶⁷ 2022 Nonresidential and Multifamily Compliance Manual, Page 2-5,

COMMENT LETTER #1

January 19, 2024

Yanrong Zhu
 Program Supervisor
 South Coast Air Quality Management District
 21865 Copley Drive
 Diamond Bar, CA 91765

Re: Rule 1146.2 Initial Preliminary Draft of Rule 1146.2

Dear Ms. Zhu:

On behalf of Bradford White Corporation (BWC), we would like to thank you for the opportunity to comment on South Coast Air Quality Management District's (SCAQMD) Initial Preliminary Draft of Rule 1146.2.

BWC is an American-owned, full-line manufacturer of residential, commercial, and industrial products for water heating, space heating, combination heating, and water storage. In Southern California, a significant number of individuals, families, and job providers rely on our products for their hot water and space heating needs. We have compiled our comments and questions to the Initial Preliminary Draft of Rule 1146.2 below:

General comments

BWC has participated in the District's five working groups related to Rule 1146.2 and has reviewed the preliminary rule language. We observe that the preliminary rule language and implementation timelines have deviated significantly from SCAQMD's 2022 Air Quality Management Plan (AQMP), where there was discussion of "infeasibility" and use of Low NOx alternatives. Specifically, C-CMB-01 stated "allow low NOx technologies as a transitional alternative when installing a zero-emission unit is determined to be infeasible." However, the Initial Preliminary Draft of Rule 1146.2 does not contain any provisions to address infeasibility of equipment, or use of Low NOx alternatives. Further, it proposes to push up the implementation timelines, as compared to the 2022 AQMP, for equipment phase out beginning in 2025, less than a year after the rule is scheduled to be adopted in April 2024.

1-1

BWC has also reviewed the staff analysis from the working group presentations, and we believe the conclusions drawn from these studies have been applied too broadly. We strongly recommend additional site evaluations are necessary to determine the market's readiness to transition to zero NOx. Water heating and boiler equipment is not limited in application to multifamily and hospitals as much of the staff analysis shows. A single commercial water heater or boiler model could be used in a wide variety of applications

Built to be the Best™

725 Talamore Drive • Ambler, PA 19002-1873 • 215-641-9400 • www.bradfordwhitecorporation.com

ranging from hotels/motels, restaurants, office buildings, and gymnasiums. Keeping this in mind, each application has its own unique challenges that must be accounted for. While zero NOx replacements could be feasible, it comes with increased cost and installation challenges, many of which are significant. We have outlined a common example below:

Cont'd
1-1

Replacing a Commercial (100 Gallon, 199,999 Btu/hr) Gas-fired Storage Water Heater

This example shows how current commercially available electric water heater product(s) could be used in lieu of a commercial gas-fired storage water heater that matches the specifications in the above subject line. These products are commonly sold for use in smaller hotels/motels, restaurants, gymnasiums, and office buildings.

	Commercial gas-fired storage water heater	Commercial ASME Tank Electric Water Heater	(2) Heavy Duty Commercial Tank Electric Water Heater	Medium Duty Commercial Tank Electric Water Heater plus 200-gallon storage tank
Input	199,999 Btu/hr or 58.59 kW	81 kW	30 kW per unit	18 kW
Amperage Requirement	5.5A	98A	36A each	22A
Recovery (100°F Rise)	235 GPH	334 GPH	124 GPH each	74 GPH
Footprint (in)	77.63"H x 28.25" W	60.88"H x 32.5" W	50.44" H x 30.5" W per unit	63" H x 30.88"W plus 78"H x 32" W storage tank
Piping	Uses existing	Uses existing	Multiple units piped in reverse return	Commercial electric paired with storage tank
Installation Challenges compared to Gas		Equipment cost premium, potential cost to upgrade service,	Equipment cost premium, Increased footprint,	Equipment cost premium, Increased footprint,

Built to be the Best™

725 Talamore Drive • Ambler, PA 19002-1873 • 215-641-9400 • www.bradfordwhitecorporation.com

	Commercial gas-fired storage water heater	Commercial ASME Tank Electric Water Heater	(2) Heavy Duty Commercial Tank Electric Water Heater	Medium Duty Commercial Tank Electric Water Heater plus 200-gallon storage tank
		panel, Increased footprint, requires ASME product, increased operation cost	Potential cost to upgrade service panel, additional labor and materials for piping, increased operation cost	ASME Product, Increased cost of piping, Recirculation pump (cost), Increased operation cost
Product Link	EF120T199	CEA80-81kW	CEHD50-30kW	E32-120R-18kW plus 200 gallon storage tank

While the example above highlights that commercially available electric products can be used to replace gas products or installed in new construction, this tradeoff comes at a premium cost for the equipment and will require additional cost and installation considerations to function properly.

In these common situations, using a heat pump water heater (HPWH) solution *may* benefit the operator by reducing the utility cost and possibly avoiding a costly upgrade to the electrical panel. However, the downside of using a HPWH is that it will require a much larger footprint, as more storage tank capacity is needed to compensate for slower recovery rates, and significant air volume is needed to transfer heat effectively. In many existing buildings, this expanded footprint can require widening doorways or closets; partially removing walls and/or ceilings; and running electrical wiring to the install area if needed. Additionally, commercial HPWHs¹ will be considerably more expensive than their gas-fired counterparts and will likely have availability concerns as these products often have longer lead times to manufacture, and may not be readily available at supply houses. These issues are especially concerning in emergency replacement situations.

Given the unique challenges water heating applications of this kind can present, BWC suggests District staff consider including rule provisions for project “infeasibility” as was originally presented in the 2022

¹ [Microsoft Word - 2021 WA Code Change - Heat Pump Water Heating](#)

Built to be the Best™

725 Talamore Drive • Ambler, PA 19002-1873 • 215-641-9400 • www.bradfordwhitecorporation.com

AQMP. BWC submitted comments on the 2022 AQMP with a suggested definition for determining whether or not a zero NOx project was feasible and reiterate this recommendation below:

Cont'd
1-1

“Where a project applicant can reasonably demonstrate that all parts and equipment required to retrofit an existing, mixed fuel building with a zero-emission water heater equipment is not:

- Commercially available;
- More costly than commercially available gas options (20% or more);
- Able to fit in the footprint of existing equipment;
- Able to meet the building/home water heating demand; and
- Available from suppliers within the district to replace inoperative equipment on an emergency basis.

In these cases, an exception shall be granted to use readily available gas Ultra Low NOx water heating equipment.”

Product Labeling

1-2

The Initial Preliminary Draft of Rule 1146.2 proposes to require manufacturers to affix labels to equipment identifying the Unit as “not to be installed or sold for New Buildings.” BWC believes the proposed labeling requirement is unnecessary to enforce the rule and will add significant cost and compliance complexity to regulated products.

SCAQMD currently maintains a qualified products list² for all manufacturer water heating and boiler models certified under Rule 1146.2. To enforce the proposed Zero NOx implementation dates, SCAQMD could simply modify their table to show models that are allowed in new construction and models that are only allowed in existing buildings. Secondly, new construction requires plans to be submitted to building jurisdictions to review, as well as Title 24 energy modeling. SCAQMD can work with building jurisdictions within their territory that review and approve project plans to enforce the use of Zero NOx water heating and boiler equipment. Lastly, new construction projects are permitted and require building inspectors to approve the construction. If a non-compliant product were to be installed, it could ultimately be flagged for removal by the building inspector.

For the reasons outlined above, BWC strongly urges staff to remove the labeling requirement as it will not aid in enforcement and will simply add cost and complexity to the manufacturing process.

Useful Life and Repairs

1-3

The Initial Preliminary Draft of Rule 1146.2 proposes to establish effective useful lives for equipment. While BWC questions how the District arrived at the stated useful lives for each product, we also have questions regarding the enforcement of useful lives. We respectfully request feedback to the following questions:

- How will SCAQMD enforce equipment operating beyond its deemed useful life?
- If affected products are still in proper working order, will the owner be required to remove and replace the product with a zero NOx product?
 - If so, will there be a timeline given? Will there be an exception process?
- What analysis did SCAQMD conduct to determine the established useful lives are appropriate?
 - Will that analysis be made available, in full, for stakeholders to review and comment on?

² [Rule 1146.2 - Emissions of Oxides of Nitrogen from Large Water Heaters and Small Boilers and Process Heaters \(aqmd.gov\)](https://www.aqmd.gov/rule-1146.2)

Built to be the Best™

725 Talamore Drive • Ambler, PA 19002-1873 • 215-641-9400 • www.bradfordwhitecorporation.com

- How will repairs be enforced?

Cont'd
1-3

As Rule 1146.2 is currently written, our understanding is an owner would be responsible for ensuring that any repair completed on a regulated water heater or boiler product burner after the zero NOx compliance date would be required to meet the new zero NOx standard.

For instance, consider a situation where a Type 1 water heater was installed on December 1, 2028, and suffered a burner failure in April 2029. Unless there was a zero NOx retrofit kit available, the owner would be compelled to replace the entire unit. Apart from potential safety concerns, attempting to retrofit an existing water heater or boiler to meet zero NOx emissions would often require significant modifications to the appliance's venting system. These modifications, such as the addition of a catalytic converter, may not be feasible in all existing buildings if the necessary zero NOx burner is incompatible with the unit. If modifications are possible, they will often represent a significant cost to the building owner if they are.

This poses an undue and significant cost to the building owner as well as other concerns. BWC recommends that unless a water heater or boiler failure results in a leaking tank, repairs to burner and other components be allowed if the equipment is within its deemed useful life, as defined in Table 2 of the rule.

Implementation Timelines

1-4

BWC recommends that SCAQMD align all new construction timelines with California Energy Commission (CEC) Title 24 Energy Code cycles. For instance, the 2025 Energy Code is currently under development and is expected to be adopted by January 1, 2025. The code does not take effect until January 1, 2026. Similarly, the following code cycle for the 2028 Energy Code, will not take effect until January 1, 2029. This change would help align SCAQMD compliance dates with changes occurring at the statewide level for designers, architects, and builders. We also recommend keeping the proposed four-year gap between new construction and existing construction compliance dates. For future rule development proceedings, we recommend SCAQMD align with state energy code cycles and Department of Energy (DOE) rulemakings.

In addition to aligning with the CEC, we recommend four additional compliance date changes.

- **Type 1 Pool Heater equipment category** align with the 2029 date for new construction and subsequently 2033 for existing construction. On May 30, 2023, the DOE published a Final Rule, which amended energy conservation standards for these products³ containing a new Integrated Thermal Efficiency (TE_i) metric to measure efficiency and sets the TE_i for gas-fired pool heaters at 84%. Additionally in this rule, the DOE is raising the efficiency requirements for electric pool heaters to effectively require the use of heat pump technology. These new requirements go into effect May 30, 2028. More closely aligning SCAQMD's proposed zero NOx compliance date with this DOE Final Rule, will help ease the burden for manufacturers, who can then be mindful of these changes, as well as those potentially adopted by SCAQMD as they work to redesign their products.
- **Type 2 (Non-High Temperature) equipment category** align with the 2029 date for new construction and subsequently 2033 for existing construction. The 2025 Energy Code is already addressing all-electric construction in smaller multifamily, hotel/motel and school building applications. Further, larger applications requiring over 1 million Btu rated input must use the highest efficiency gas equipment to achieve a combined rated efficiency of 90% Thermal Efficiency or better. In addition to Title 24, manufacturers will already have a significant challenge meeting the already finalized DOE Commercial Water Heater Energy Conservation Standards

³ [Federal Register :: Energy Conservation Program: Energy Conservation Standards for Consumer Pool Heaters](#)

Built to be the Best™

725 Talamore Drive • Ambler, PA 19002-1873 • 215-641-9400 • www.bradfordwhitecorporation.com

requirements⁴. These changes go into effect on October 6, 2026, and effectively will require all commercial storage water heaters to meet a 95% Thermal Efficiency.

- **The Instantaneous Water Heater category** be split into two categories with different compliance dates:
 - *Gas-fired instantaneous water heater* (as further defined below) with a nameplate input rating less than 200,000 Btu/hr equipment category align with the 2026 date for new construction and subsequently 2030 for existing construction. This category is predominantly used in residential new construction and the 2025 Energy Code is already proposing a HPWH baseline for residential new construction. Adopting a January 1, 2026, compliance date for this category and subsequently a 2030 date for existing construction would better align with statewide efforts to reduce emissions in new construction and make for an easier transition.
 - *Instantaneous Water Heater* (as further defined below) with a nameplate input rating greater than 200,000 Btu/hr equipment category align with the 2029 date for new construction and subsequently 2033 for existing construction. These products also fall under the DOE efficiency changes on October 6, 2026, discussed above and will require all instantaneous water heaters to meet a 96% Thermal Efficiency.

Cont'd
1-4

Our summary of proposed changes to compliance dates and equipment categories is contained in the following table:

Equipment Category	NOx and CO Emission Limits (ppmv)	Building Type	Compliance Date	Useful Life (years)
Type 1 Unit	0	New/Existing	Jan. 1, 2026/Jan 1, 2030	15
Gas-fired instantaneous water heater (≤200,000 BTU)	0	New/Existing	Jan. 1, 2026/Jan 1, 2030	25
Instantaneous Water Heater (>200,000 BTU)	0	New/Existing	Jan. 1, 2029/Jan 1, 2033	25
Type 1 Pool Heater	0	New/Existing	Jan. 1, 2029/Jan 1, 2033	15
Type 2 Unit	0	New/Existing	Jan. 1, 2029/Jan 1, 2033	25
Type 1 High Temperature Unit	0	New/Existing	Jan. 1, 2029/Jan 1, 2033	25
Type 2 High Temperature Unit	0	New/Existing	Jan. 1, 2029/Jan 1, 2033	25

Lastly, we ask the District to clarify in the rule, that the proposed compliance dates for existing buildings are based on date of equipment manufacture, and not an effective date.

⁴ [2023-20392.pdf \(govinfo.gov\)](https://www.govinfo.gov/2023-20392.pdf)

Definitions

BWC recommends that SCAQMD align their equipment category definitions with the Code of Federal Regulations. The Code of Federal Regulations governs certain regulated products, including those covered by this rulemaking. By adopting these definitions in Rule 1146.2, SCAQMD can harmonize their rule with how products are built in the United States and avoid creating product classes specific to one region of southern California. Additionally, by adopting these definitions, compliance with NO_x emission standards is made simpler as manufacturers are not sorting each product class by Btu/hr to determine which model units comply. The specific equipment category changes we propose are as follows:

- **Type 1 and Type 2 (Non-High Temperature Units):** This category includes all *Storage water heaters* and *Residential-duty commercial water heaters* as defined in 10 CFR 431.102⁵
 - “*Storage Water Heater* means a water heater that uses gas, oil, or electricity to heat and store water within the appliance at a thermostatically-controlled temperature for delivery on demand, including:
 1. Gas-fired storage water heaters with a rated input both greater than 75,000 Btu/hr and less than 4,000 Btu/hr per gallon of stored water
 2. Oil-fired storage water heaters with a rated input both greater than 105,000 Btu/hr and less than 4,000 Btu/hr per gallon of stored water; and
 3. Electric storage water heaters with a rated input both greater than 12 kW and less than 4,000 Btu/hr per gallon of stored water.”
 - “*Residential-duty commercial water heater* means any gas-fired storage, oil-fired storage, or electric instantaneous commercial water heater that meets the following conditions:
 1. For models requiring electricity, uses single-phase external power supply;
 2. Is not designed to provide outlet hot water at temperatures greater than 180 °F; and
 3. Does not meet any of the following criteria:

Water heater type	Indicator of non-residential application
Gas-fired storage	Rated input >105 kBtu/hr; Rated storage volume >120 gallons.
Oil-fired storage	Rated input >140 kBtu/hr; Rated storage volume >120 gallons.
Electric instantaneous	Rated input >58.6 kW; Rated storage volume >2 gallons.

- **Type 1 and Type 2 High Temperature Units:** This category includes *Hot water supply boilers*⁶ and *Commercial package boiler* as defined in 10 CFR 431.102
 - “*Hot water supply boiler* means a packaged boiler (defined in § 431.82 of this part) that is industrial equipment and that:
 1. Has a rated input from 300,000 Btu/hr to 12,500,000 Btu/hr and of at least 4,000 Btu/hr per gallon of stored water;
 2. Is suitable for heating potable water; and
 3. Meets either or both of the following conditions:

⁵ [eCFR :: 10 CFR 431.102 -- Definitions concerning commercial water heaters, hot water supply boilers, unfired hot water storage tanks, and commercial heat pump water heaters.](#)

⁶ [eCFR :: 10 CFR 431.102 -- Definitions concerning commercial water heaters, hot water supply boilers, unfired hot water storage tanks, and commercial heat pump water heaters.](#)

Built to be the Best™

725 Talamore Drive • Ambler, PA 19002-1873 • 215-641-9400 • www.bradfordwhitecorporation.com

- i. It has the temperature and pressure controls necessary for heating potable water for purposes other than space heating; or
 - ii. The manufacturer's product literature, product markings, product marketing, or product installation and operation instructions indicate that the boiler's intended uses include heating potable water for purposes other than space heating.
- "Commercial package boiler means a packaged boiler that meets all of the following criteria:
 - 1. Has rated input of 300,000 Btu/hr or greater;
- **Instantaneous Water Heater Units:** This category includes *Instantaneous water heaters*⁷ as defined in 10 CFR 431.102 and *Gas-fired instantaneous water heaters*⁸ as defined in section 10 CFR 430.2
 - "Instantaneous water heater means a water heater that uses gas, oil, or electricity, including:
 - 1. Gas-fired instantaneous water heaters with a rated input both greater than 200,000 Btu/hr and not less than 4,000 Btu/hr per gallon of stored water;
 - 2. Oil-fired instantaneous water heaters with a rated input both greater than 210,000 Btu/hr and not less than 4,000 Btu/hr per gallon of stored water; and
 - 3. Electric instantaneous water heaters with a rated input both greater than 12 kW and not less than 4,000 Btu/hr per gallon of stored water."
 - "Gas-fired instantaneous water heater means a water heater that uses gas as the main energy source, has a nameplate input rating less than 200,000 Btu/hr, and contains no more than one gallon of water per 4,000 Btu per hour of input."

Cont'd
1-5

While the definitions above contained in the Code of Federal Regulations do not exactly align with SCAQMD's Btu/hr limits for Type 1 and Type 2, these definitions have little to no bearing on the proposed compliance dates. Specifically for Type 1 and Type 2 High Temperature units, SCAQMD proposes the same compliance dates, covering the entire Btu/hr range. We strongly believe these definition changes need to be adopted into Rule 1146.2 to align with federal equipment categories and provide additional clarity.

In closing, we would like to reiterate the need for SCAQMD to align compliance dates with Title 24 Energy Code cycles and update equipment category definitions to align with the Code of Federal Regulations. We fully understand the District's goals to reduce emissions and want to play a part in ensuring it is successful in responsibly doing so. We welcome continued dialogue on this matter and would be pleased to have further, direct, conversations with District staff.

BWC is grateful to SCAQMD for the opportunity to provide feedback on the Initial Preliminary Draft of Rule 1146.2. Please let me know if you have any questions or would like to schedule a meeting to discuss our comments further.

Respectfully Submitted,

Bradford White Corporation

RESPONSE TO COMMENT LETTER #1

Response to Comment 1-1:

Staff appreciates Bradford White Corporation's comments on PAR 1146.2. The 2022 AQMP's objective is to transition to zero-emission technologies wherever feasible. Staff identified technically feasible zero-emission control options for each category of equipment subject to Rule 1146.2 as discussed in Chapter 2 of this report. Allowing alternative control options (e.g., near-zero-emission technology) would not meet the air quality objectives.

The 2022 AQMP Control Measure C-CMB-01 set a goal for zero-emission standard by 2031 for all equipment categories, wherever feasible. PAR 1146.2 is consistent with this goal and has proposed a more specific schedule for each equipment category, with three implementation phases depending on building and technology readiness. Units for Phase I are more ready for zero-emission implementation and thus has an earlier implementation date. Units for Phase III require additional time for technology development and thus have a later implementation. Nevertheless, staff extended the Phase I compliance date for new buildings by one year, from 2025 to 2026, to better align with the CEC Building Code effective date.

Staff held meetings and conducted site visits for various applications including food service, grocery, hotel, hospital, multifamily, office building, and dry cleaning. Staff recognizes there are many applications with unique situations and proposed alternative compliance options to address these specific concerns.

Staff appreciates the example of replacing a gas-fired unit with an electric resistance water heater. Staff recognizes that heat pumps can be over three times more efficient than electric resistance technologies, which can lower fuel switching and operational costs. Further discussion on cost-effectiveness, including capital and installation costs, are included in Chapter 2 of this staff report. There are some commercial incentives available including the Willdan Commercial Energy Efficiency Program, which provides incentives to commercial customers who have monthly maximum energy demands of greater than 20 kW across Southern California Edison's service territory.

For further discussion on spacing, please refer to Response to Comment PW-2.

Response to Comment 1-2:

PAR 1146.2 proposes a labeling requirement under the new subdivision (j) for the period between the new building compliance dates and existing building compliance dates of each equipment category. Paragraph (j)(1) requires labeling for units to be installed in existing buildings, and paragraph (j)(2) requires labeling for instantaneous water heaters rated less than or equal to 200 kBtu/hr installed in mobile homes. Labeling requirements are being proposed to address concerns for how the limits will be enforced when new buildings are required to have zero-emission units limits installed while existing buildings are allowed to have units that meet 20 ppmv NO_x limits installed. Staff recognizes the need for a compliance tool to differentiate the units allowed to be installed in new and existing buildings. Please also see Response to Comment PC-9 for more details.

Response to Comment 1-3:

South Coast AQMD has a Compliance and Enforcement team that conducts inspections. If a unit is deemed to be operating past its unit age after PAR 1146.2 Table 3 compliance dates are in effect, the owner or operator would be required to replace the unit with a zero-emission unit. Units installed in residential structures are exempt from this retrofit requirement. Further discussion on unit age for different categories can be found in Chapter 2 of this staff report. In previous Rule 1146.2 rulemaking, unit age of 15 years was utilized for the analysis. Meetings and site visits with different manufacturers during the current rulemaking process indicated unit ages of under and over 25 years for gas-fired units. U.S. DOE estimates that with proper installation and maintenance, heat pump pool heaters can last 10 or more years. The BAAQMD staff report for Rules 9-4 and 9-6 indicated that water heaters were assumed to have an average lifespan of 13 years. For PAR 1146.2, staff utilized 15 years for Type 1 units that are not instantaneous water heaters or high temperature units and utilized 25 years for other categories. Staff believes the proposed unit age for each category of this proposed amended rule is appropriate and aligns closely with other rulemakings, while taking into consideration manufacturer comments.

PAR 1146.2 subdivision (i), as explained in Chapter 3 of this staff report, provides alternative compliance options to address specific concerns including emergency replacement, utility upgrades, replacement of five or more units within consecutive two compliance years, and other cases.

Paragraph (d)(5) of PAR 1146.2 specifies the applicable emission limit when an owner or operator modifies or replaces a burner. A unit requiring burner replacement will be subject to zero-emission if the burner replacement occurs after PAR 1146.2 Table 3 zero-emission compliance dates and the unit has reached its unit age. Otherwise, Table 2 emission limits for 20 ppmv NO_x, and 400 ppmv CO for type 2 unit, will apply.

Response to Comment 1-4:

Where appropriate, staff aligned the compliance dates with the effective dates of other agencies. Staff extended the Phase I compliance date for new buildings by one year, from 2025 to 2026, to align with the CEC Building Code effective date. However, staff does not see a compelling reason to align with the 2029 effective date for the future Building Code for which the requirements are yet unknown, or to extend other compliance dates to keep the four-year gap between new building and existing building compliance dates in the initial proposal. Staff set compliance dates to take into account the upcoming 2026 effective year for the CEC Building Code, the BARCT assessment, and feedback from stakeholders.

Staff acknowledges the 84 percent efficiency set by U.S. DOE for gas-fired pool heaters and did reflect this efficiency in the revised calculations. Staff recognizes that the DOE final rule will apply to efficiency standards for electric pool heaters, which is not directly applicable to PAR 1146.2, which is focused on reducing NO_x emissions. Staff extended the Phase II compliance date for new buildings by one year, from 2027 to 2028, to allow more time for technology to mature. Staff strives to align with other agencies on timelines, but mainly relies on the South Coast AQMD's independent BARCT assessment to establish the appropriate compliance schedule. PAR 1146.2 provides shorter timelines for

units where the BARCT assessment indicated that zero-emission technology is available now, and longer timelines where the BARCT assessment indicates more time is needed.

Staff recognizes that the 2025 Energy Code is already addressing all-electric construction in smaller multifamily, hotel/motel and school building applications. Staff extended the Phase II compliance date for new buildings by one year, from 2027 to 2028, which will include the Type 2 (non-high temperature unit) category.

Staff divided instantaneous water heaters into two categories by rated heat input capacities as suggested so that larger units will have more time to comply. Further, staff extended the Phase I compliance date for new buildings by one year, from 2025 to 2026, to align with the CEC Building Code effective date.

For clarification regarding the zero-emission compliance dates for existing buildings, they are effective dates for new installations applicable to the supply chain including manufacturers, distributors, sellers, and installers. They are also the effective dates for the retrofit requirement applicable to owners and operators, after which units are required to be phased into the zero-emission technologies once their unit age as listed in Table 2 is reached.

Response to Comment 1-5:

Staff revised the high temperature unit definition by changing the temperature threshold from 190 degrees Fahrenheit to 180 degrees Fahrenheit, as was recommended by stakeholders to align with the Code of Federal Regulations definition for “residential-duty commercial water heater” for outlet water temperature. Staff divided instantaneous water heaters into two categories by rated heat input capacities as suggested. Staff notes that PAR 1146.2 applies to natural gas-fired units, and the definitions detailed by the commenter include fuel types other than natural gas.

Diamond Bar, CA 91765

RE: 1146.2 Public Workshop Comments

Dear Mr. Krause,

Thank you and your staff for the ongoing opportunity to discuss Proposed Rule 1146.2. Navien will be making comments in the Public Workshop tomorrow and wanted to provide those in writing as well.

As we have previously noted, Navien's tankless water heaters fall between 1121's residential rules and 1146.2 commercial rules. However, Navien tankless water heaters are mostly used in residences and are for use by consumers. Therefore, we believe that the compliance date for tankless water heaters should align with other residential products covered under 1121.

2-1

Further, we encourage staff and the Board to give careful consideration to the detailed definitions and revised implementation timelines spelled out in the Bradford White letter of January 19, 2024. Navien agrees with Bradford White that implementation timelines should match the **California Energy Commission Title 24 Energy Code** of January 1, 2026, compliance dates for new buildings. Furthermore, SCAQMD should maintain a four-year gap between new and existing construction where it is anticipated for Department of Energy (DOE) to implement new efficiency targets in 2030, to align and be consistent with DOE.

2-2

Moreover, we believe the staff report's number of 300,000 tankless water heaters in the South Coast Basin is low, perhaps by as much as two to three times. Navien alone has sold more than 200,000 tankless units in the Basin. Since our units are more efficient than non-condensing units, we believe the NOx reductions achieved by replacing these units are over-estimated and the costs to consumers will be greater than estimated, and we request the final staff report to consider these factors.

2-3

20 Goodyear, Irvine, CA 92618

T 949.420.0420

F 949.420.0430

W Navieninc.com

Page 2 of 2
SCAQMD
February 6, 2024

Finally, we request staff clarify its intentions about the useful life/repairs section of the Proposed Rule. Under "burner replacement" scenarios, when it is **after** the compliance date and the unit has **not** reached useful life, must we then comply with Table 1 Emission Limit? If any part other than a burner needs to be replaced, then are we correct that Table 2 compliance shall not be applicable since the parts are not related to emissions? We note that the lack of clarity of this section points to additional future enforcement challenges.

2-4

Again, thank you for the opportunity to share our concerns with the AQMD. We look forward to your responses and to working together to improve air quality in our region.

Sincerely,

A handwritten signature in black ink, appearing to read "KPI", is written over a light blue horizontal line.

KEVIN PIROTIN
Vice President
Engineering & Service
Navien, Inc.

RESPONSE TO COMMENT LETTER #2**Response to Comment 2-1:**

Staff appreciates Navien's comments on PAR 1146.2 and input on the rule language. For clarification, PAR 1121 rulemaking is in progress with an anticipated public hearing date in the fourth quarter of 2024. Instantaneous water heaters are not subject to PAR 1121, even though they are mostly installed in residential structures similar to PAR 1121 units. Building readiness is being evaluated for both PAR 1146.2 and PAR 1121. Staff will consider aligning compliance dates and determining if further analysis of technologies and other factors for PAR 1121 will require any different implementation timelines.

Response to Comment 2-2:

Staff extended Phase I compliance date for new buildings by one year, from 2025 to 2026, to better align with the CEC Building Code effective date. Please refer to Response to Comment 1-4 for more detail.

Response to Comment 2-3:

Staff estimated the instantaneous water heater universe to be approximately 300,000 units in the South Coast AQMD region using the 2019 California RASS from the CEC and the RECS from the U.S. Energy Information Administration. Staff appreciates any detailed estimate and data source on the number of instantaneous water heaters in the region. Staff understands instantaneous water heaters can be more efficient than non-condensing units, the 95% energy efficiency used in the cost-effectiveness calculations for instantaneous water heaters aligns with their energy efficiency level.

Response to Comment 2-4:

Paragraph (d)(5) specifies the applicable emission limit when an owner or operator modifies or replaces a burner. Zero-emission limits in Table 2 will only apply when the modification or replacement occurs on and after the Table 3 compliance date and the unit has reached its unit age; otherwise, Table 1 limits apply. Paragraph (d)(5) specifies that this is for a burner modification or replacement. If any part other than a burner needs to be replaced, Paragraph (d)(5) is not applicable. This provision was added to address a stakeholder's concern that a burner replacement might occur before the end of a unit's unit age resulting in stranded assets.

Diamond Bar, CA 91765
mkrause@aqmd.gov
hfarr@aqmd.gov

Re: Proposed Rule 1146.2

Dear Mr. Krause and Ms. Farr:

The undersigned organizations are grateful for the opportunity to comment on Proposed Amended Rule 1146.2. The current proposal – the second major regulation targeting Nitrogen Oxide (NOx) emissions after adoption of the 2022 Air Quality Management Plan (AQMP) - marks an important milestone, in that the Air District including zero-emission standards for all equipment covered under the rule. We support moving swiftly to adoption of a true zero-emission regulation. The points below provide feedback on the most recent iteration of the rule and the presentation at Working Group Meeting 5 in December of 2023.

I. Great Urgency Exists to Pass This Regulation.

3-1

There is great urgency to move forward with these rule amendments no later than the April Governing Board meeting, the proposed date presented at the last Working Group Meeting. The region has failed to attain even the 1997 8-hour ozone standard, much less any of the subsequent ozone standards. The region has also failed to attain the annual PM2.5 standard. The NOx emission reductions achieved by these rule amendments will help the Air District make progress on attainment for both pollutants, resulting in significant health benefits for residents. In addition to banking critical emission reductions, timely adoption of this regulation will maximize lead time for market and complementary policy development and allow staff to move onto other life-saving rules that are dearly needed. It is concerning that Slide 42 of the presentation for Working Group Meeting #5 noted that the April adoption hearing timeline could be “subject to change.” We highly encourage staff not to delay this rulemaking.

The South Coast AQMD has already delayed these amendments to Rule 1146.2. During Working Group Meeting #1 in April of 2023, the AQMD staff projected that these rule amendments were going to be adopted in September of that year. That timeline was later moved

down to November 2023, then over to the first quarter of 2024, before landing on the current proposed date in April 2024.

Cont'd
3-1

While we generally understand the motivation behind these timeline changes and have not opposed moving the adoption date, the April 2024 proposal is already a delay of seven months from the proposal originally presented to the public, and we would be unlikely to support additional delays.

As the Air District is aware, these delays have real and serious consequences for public health. The 2022 Air Quality Management Plan (AQMP) makes clear that passing zero-emission regulations for stationary sources must be a top priority. The AQMP aptly states:

Previous AQMPs have relied on increasingly stringent regulations targeting tailpipe and exhaust stack emissions, new engine technologies, or fuel mix improvements. However, these approaches rely on additional reductions from already strictly regulated sources and cannot achieve an additional 67 percent reduction beyond the 2037 baseline. Therefore, there is no viable pathway to achieve the needed reductions without widespread adoption of zero emissions (ZE) technologies across all mobile sectors and stationary sources, large and small.¹

With so many control measures needing to be accomplished in the near term, the Air District must quickly pass zero-emission regulations on these sources and others. Moreover, given that some facilities covered under these rules will be changing equipment due to the REgional CLean Air Incentives Market (RECLAIM) transition, setting these standards sooner will provide a stronger signal to focus on advancing zero-emission solutions instead of continued combustion technologies.

We support the April adoption date for these amendments and urge that the AQMD stick to this timeline for passing this important life-saving regulation.

II. Zero--Emission Standards Are Critical, and Faster Compliance is Feasible.

3-2

Moving to zero-emission equipment where feasible remains critical to attaining federal and state ozone and PM2.5 standards, and our organizations are pleased that this regulation includes zero-emission standards for all categories of equipment:

¹ See 2022 Final AQMP, at ES-4, available at <http://www.aqmd.gov/docs/default-source/clean-air-plans/air-quality-management-plans/2022-air-quality-management-plan/final-2022-aqmp/final-2022-aqmp.pdf?sfvrsn=16>.

Modify Requirements:

- Present future effective limits in table format

(2) No person shall manufacture, supply, sell, offer for sale, or install, for use in the South Coast AQMD, any Unit subject to this rule, unless such Unit does not exceed the applicable NOx and CO emission limit and compliance date set forth in Table 2.

Table 2 – NOx and CO Emission Limits, Compliance Schedule, and Unit Useful Life

Equipment Category	NOx and CO Emission Limits (ppmv)	Building Type	Compliance Date	Useful Life (years)
Type 1 Unit*	0	New	January 1, 2025	15
		Existing	January 1, 2029	
Instantaneous Water Heater	0	New	January 1, 2025	25
		Existing	January 1, 2029	
Type 1 Pool Heater	0	New	January 1, 2027	15
		Existing	January 1, 2031	
Type 2 Unit**	0	New	January 1, 2027	25
		Existing	January 1, 2031	
Type 1 High Temperature Unit	0	New	January 1, 2029	25
		Existing	January 1, 2033	
Type 2 High Temperature Unit	0	New	January 1, 2029	25
		Existing	January 1, 2033	

* Referring to a Type 1 Unit that is not a High Temperature Unit, Type 1 Pool Heater, or Instantaneous Water Heater.

** Referring to a Type 2 Unit that is not a High Temperature Unit.

34

Some compliance dates can and should be moved up, however. Importantly, given the need for additional NOx reductions by 2031 to attain the 2008 8-hour ozone standard after more than 20 years of excess impacts to health and air quality, all equipment categories currently listed with 2033 compliance dates should be shifted to 2031. Maximizing emissions reductions in the District by 2031 will be necessary to avoid further years of nonattainment and its concomitant harms to residents of the region.

In a similar vein, equipment categories currently listed with 2029 compliance dates should be bumped up to 2028 in order to allow for a greater penetration of equipment before the 2031 attainment deadline arrives.

III. The Current Approach of Assuming Natural Gas Will Be Abundant and Cheap for Decades Does Not Comport with Reality.

3-3

On December 1, 2022, the California Public Utilities Commission (CPUC) “adopted a new framework to comprehensively review utility natural gas infrastructure investments in order to help the state transition away from natural gas-fueled technologies and avoid stranded assets in the gas system.”² There is a cognitive dissonance between air quality planning and these proceedings happening at the state level. The current BARCT assessments assume electricity prices will go up over the next two decades, but natural gas prices are predicted to go down.

These assumptions arise from South Coast AQMD’s use of the gas and electricity rate projections included in the California Energy Commission’s (CEC) California Energy Demand

² CPUC Creates New Framework to Advance California’s Transition Away from Natural Gas, Press Release, (December 1, 2022), available at <https://www.cpuc.ca.gov/news-and-updates/all-news/cpuc-creates-new-framework-to-advance-california-transition-away-from-natural-gas>.

Update 2022-2035³ – which assumes gas demand will remain steady through time despite California’s many policies to reduce fossil fuel use and corresponding greenhouse gas emissions.⁴

Cont'd
3-3

The economic assumptions underpinning the analysis that fossil methane will be cheap and abundant ignore many factors. For example, as more and more people and entities leave the gas system, fewer and fewer users will remain to pay for the fixed infrastructure costs of the increasingly expensive gas system. It is not clear why gas prices in the South Coast Air Basin would defy the tenets of economics and remain cheap for decades to come.

The same year CEC published the document staff is using, the agency published another report, “The Challenge of Retail Gas in California’s Low-Carbon Future,” which takes future demand and future customer base into account and that work finds that gas rates will increase steadily over time especially as California implements its programs to curb air and climate pollution.⁵ For example, the chart below shows that building electrification at a high level will result in increased rates for industrial facilities.

³ California Energy Demand Update available at <https://www.energy.ca.gov/data-reports/reports/integrated-energy-policy-report/2022-integrated-energy-policy-report-update-2>.

⁴ The Environmental Defense Fund (EDF) filed significant comments on the gas assumptions portion of the Integrated Energy Policy Report (IEPR). In particular, EDF pointed out “Currently, the IEPR preliminary model projects stable future gas demand...”

EDF highlights two concerns around these projections. First, stable gas demand is at odds with California’s climate policies aimed at reducing fossil fuel use—including natural gas demand. These state policies include the Senate Bill 32 targets of reducing California’s greenhouse gas emissions by 40% below 1990 levels by 2030, the Assembly Bill 1279 target of reaching net zero by 2045, the California Air Resources Board (CARB) 2022 Scoping Plan targets of reducing total fossil fuel consumption by 86% below 2022 levels by 2045, the California Public Utilities Commission (CPUC) decision to eliminate gas extension subsidies, and various local ordinances on gas appliances...

Second, EDF contends that it is unreasonable to assume constant demand beyond a future point in time simply because no existing projections are available. It is true that no future projection can be made with 100% confidence and accuracy; and that confidence will decline further out into the future the projection is made. However, the entire IEPR process has uncertainty of projections baked in, and holding this one element constant is not worthy of the IEPR process. To project *no change* and assume constant future gas demand beyond a certain point, however, would be to overlook existing market trends of electrification and various state policies.”

EDF Comments on Gas Demand Forecasts in IEPR, (May 2, 2023).

⁵ CEC, *The Challenge of Retail Gas in California’s Low Carbon Future*, available at <https://www.energy.ca.gov/sites/default/files/2021-06/CEC-500-2019-055-F.pdf>.

Cont'd
3-3

The CEC is currently working on its 2023 Integrated Energy Policy Report (IEPR), which is examining load modifier scenarios, including additional achievable fuel substitution through policies like zero-emission appliance standards. These scenarios are still overly conservative – for example, most assume that SCAQMD will take no action in this area, and CARB’s own statewide zero-emission standards to come are not examined at all – however the agency should monitor the 2023 IEPR process and integrate its updated gas rate projections into BARCT analyses when available.

The context for the assumptions staff use in the BARCT analysis is important as well. While the South Coast AQMD’s primary regulatory concern is reducing traditional criteria pollutants, there is overwhelming consensus that we must dramatically drive down the use of methane to stave off the worst consequences of climate change. The sector being discussed today is a large user of gas, and this rule provides great opportunity for reductions in climate pollution.

As such, equipment covered by this rule will be a priority target for addressing greenhouse gas emissions moving forward. Moreover, we are disappointed in the approach of some working group participants seeking to drop anchors in the process for achieving zero-emissions. We do not have time for delays and half measures to clean up this equipment.

IV. Our Organizations Support the Definition of “High Temperature Unit.”

3-4

At the workshop, staff requested feedback on the definition of “high temperature unit.” The current temperature is set at 190 degrees Fahrenheit. Commenters question the premise here that arbitrary temperature levels should dictate the speed of clean up of equipment. We also question any presumption – whether express or implied – of the infeasibility of zero-emissions technologies for equipment above 190 degrees. Not only are there zero-emission alternatives like electric boilers available now that can provide zero-emission heat, it is safe to assume that technology will only improve in the coming years as technology forcing regulations such as 1146.2 are implemented. Given technology development is not static, we suggest staff build into its technology review an assessment of this “high temperature unit” definition as technology continues to advance.

V. Technology Investments.

3-5

Record amounts of funding exists for addressing emissions. The South Coast AQMD Technology Advancement team should work to secure funding for incentive programs to advance zero-emissions equipment in this sector. Given the proposed rule’s zero-emission market signal, it will be important to develop an incentive program in the next couple of years before

compliance dates for existing buildings arrive. As such, the AQMD should establish a \$25 million program, including technical assistance to support entities that want to advance zero-emission technologies quicker than proposed deadlines for equipment covered by this rule. These monies could come from state or federal funds, such as the Food Production Investment Program and the Industrial Decarbonization and Improvement of Grid Operations program, which are administered by the California Energy Commission.

Cont'd
3-5

VI. Technology Summit.

3-6

The technological changes in this sector are rapidly evolving. To play its proper leading role in this area, SCAQMD should participate in and/or host a technology workshop focused on equipment covered by this rule and other related sectors (e.g., residential space and water heating, or industrial heat). This workshop should be conducted in coordination with our energy agencies (CEC and CPUC), in addition to our electric utilities, and it could be held regularly to capture a variety of sectors and technologies.

As an interim step, we recommend that the South Coast AQMD staff invite the Industrial Heat Pump Alliance to present to the Stationary Source Committee about new clean industrial heat solutions and what the agency can do to start eliminating more sources of health-harming and climate-disrupting fossil fuel combustion.

We appreciate your consideration of these comments, and we look forward to the adoption of these rule amendments to get one step closer to the emissions reductions the region desperately needs.

Sincerely,

Adrian Martinez
Earthjustice

David Diaz, MPH

Kim Orbe
Sierra Club, Angeles Chapter

RESPONSE TO COMMENT LETTER #3

Response to Comment 3-1:

Staff thanks the Coalition for their participation and comments on PAR 1146.2. Staff recognizes the need to pursue emission reduction with an earlier timeframe to address the air quality needs of the South Coast Air Basin. At this time, the public hearing has been further delayed; however, staff is seeking a June 2024 Public Hearing.

Response to Comment 3-2:

Staff recognizes the need for earlier compliance timelines to encourage greater adoption of zero-emission equipment before attainment deadlines. The proposed compliance dates in PAR 1146.2 Table 3 will allow for greater technology and market development to occur. In addition, staff is proposing to conduct a status check-in/technology review before ~~January 1, 2028~~[June 1, 2027](#), to assess the technology development and market availability of zero-emission units. The compliance dates also align with the goal set by the 2022 AQMP Control Measure C-CMB-01.

Response to Comment 3-3:

For cost-effectiveness calculations, staff utilized the CEC's Integrated Energy Policy Report (IEPR), which is released every two years and reports projected future rates of gas and electricity. Previously, staff utilized the 2021 IEPR for the PAR 1146.2 cost-effectiveness assessment, which impacts the cost to switch from natural gas-fired units to heat pumps. Staff has updated the cost-effectiveness assessment according to the new IEPR released on January 1, 2024, which projected natural gas rates increased by 40 percent and projected electricity cost showed a more moderate increase of 28 percent. Utilizing these new projected rates improved cost-effectiveness estimates. Staff recognizes that this is an estimate, and that future projections and actual prices may differ. A technology assessment scheduled for before ~~January 1, 2028~~[June 1, 2027](#), will consider changes in rate forecasts and integrate updated gas rate projections into BARCT analyses when available. Staff also acknowledges that California's many policies to reduce fossil fuel use and corresponding greenhouse gas emissions will lower gas demand over time, leading to increased gas costs. Staff also recognizes that there are co-benefits to reducing NOx emissions from this universe.

Response to Comment 3-4:

Staff included a high temperature unit definition with threshold of 180 degrees Fahrenheit, aligning with the Code of Federal Regulations definition for "residential-duty commercial water heater" for outlet water temperature, to provide a later implementation date for zero-emission units in this category. As discussed in Chapter 2 of this report, staff has identified some technologies that can provide hot water beyond the 180 degrees Fahrenheit threshold; however, high efficiency technology (e.g., heat pump) for this equipment category may not be mature in the market yet. While electric resistant boiler for high temperature is a mature technology, it is not viable to heavily rely on this technology due to its high-power demand that could overburden the grid. PAR 1146.2 provides a separate equipment category for high temperature units which will allow for further technology development and market

advancement prior to compliance dates. A technology assessment scheduled for before June 1, 2027, will consider the technology development and market availability of high temperature units, including whether the “high temperature unit” category should remain at the later implementation date as technology continues to advance.

Response to Comment 3-5:

Staff understands the challenge of higher upfront cost and is in the process developing a rebate program to help lower the cost for some consumers. The initial phase of the program will include incentives to water heating zero-emission technologies for small businesses that are subject to this rule. In addition, staff is requesting the third-party contractor that implements the program help direct applicants to other state, federal, and local funding opportunities that can be stacked with the South Coast AQMD rebate program. There are many funding opportunities currently available or targeted for the near future that staff will work toward securing to help defer the upfront costs to transition to zero-emission technologies.

Response to Comment 3-6:

Staff appreciates the recommendation to hold a technology workshop or summit and the suggestion to invite the Industrial Heat Pump Alliance to present to the Stationary Source Committee about new clean industrial heat solutions. Staff will consider these ideas for future meetings.

COMMENT LETTER #4**Benz Air Engineering, Co. Inc.**

CLEAN AND INTELLIGENT ENERGY SOLUTIONS

LAS VEGAS, NV - LOS ANGELES, CA - MODESTO, CA - PORTLAND, OR

February 7, 2024**Public comment PAR1146.2**

Benz Air Engineering Co, INC, ("BAE") files these comments in response South Coast Air Quality Management District's (SCAQMD) Initial Preliminary Draft of Rule 1146.2

About BAE

Having expertise in electrical generation and all aspects of steam, its generation and use, and driven by its vision of the affordable, reliable, net-zero carbon grid of the future, BAE has developed and commercialized a new steam generation technology – the hybrid Boiler Accessory – decarbonizing existing hard to electrify boilers and fluid heaters with renewable electrical power when available while providing local power at less than half the current grid heat rate. BAE's boiler accessory offers a unique capacity and energy solution that simultaneously addresses the critical AND immediate need to reduce greenhouse gas and criteria pollutant emissions, while also providing a near-term use of excess renewable electric production.

Modular and scalable, BAE's boiler accessory leverages existing hard-to-electrify emission sources as a heat and electrical energy sink, amplifying the carbon reduction of excess renewable electrical generation and firming California's grid at half the carbon rate of the highest known efficient electric generation. Depending on the grid supply, BAE's Boiler Accessory can utilize up to the limit of the existing facility's electrical supply to directly reduce greenhouse gas emissions from generating hot water or steam in a wide range of commercial and industrial applications. As the electrical grid transitions from periods of high renewable generation to generation supplied by traditional greenhouse gas emitting combined cycle generation and higher carbon single cycle sources such as fuel cells and linear generators, BAE's flameless Boiler Accessory complements fluid heaters and boilers to provide the most efficient incremental use of fuel, resulting in a net heat rate of just 4000btu/kw/hr HHV – less than half the carbon intensity of any local generation technology such as linear generators. BAE's inverter-based technology offers the widest range of valuable grid and environmental benefits including the fastest transition from consuming renewable electricity to generating ultra-low NOx and carbon emission electricity, the only known way to decarbonize hard-to-electrify emissions sources such as boilers while firming the grid at less than half the carbon footprint of microturbines, linear generators or fuel cells.

BAE's commitment to developing cost-effective and maximal efficiency heat and power generation technologies that support our nearly overloaded electrical grid infrastructure and prioritize ultra-low greenhouse gas emissions implores our public response to the AQMD's proposed regulation PAR 1146.2.

BAE provides the following comments on this preliminary draft of Rule PAR1146.2 Through these comments, we strongly recommend...

1. **AQMD EMISSION INVENTORY** analysis must include greater consideration for electrical service availability. 4-1
 - a. There are many areas within Southern California where there is insufficient electrical grid capacity to accommodate the added electrical load needed to electrify existing 1146.2 emission sources, precluding these sources from increasing their grid demand to accommodate the electrification of their 1146.2 equipment. This critical oversight must be accounted for in any EMISSION INVENTORY analysis either through the inclusion of individually reported demand from inventoried facilities and/or grid demand capacity for substation localities via the U.S Energy Information Administration¹.
 - b. of the **EMISSION INVENTORY**, there requires a determination of Technology Readiness Level of the proposed zero NOx heat pump technology. While generating sub 180F hot water via heat pump technology is available, heat pump generation of higher temperature water does not exist. Indeed, the staff report acknowledges that the zero-emission technology is “continuing to develop”² citing a public relations article about AtmosZero doing a “pilot study” at New Belgium Brewing³. A pilot study is anything but a product that is available or deployable on the scale of PAR 1146.2.
2. The **EMISSION REDUCTIONS** must include the analysis of electrical grid heat rate – the average BTU/kw-hr of the electricity supplied via the electrical grid in order accurately to determine NOx reductions. 4-2
 - a. Whereas electrical generation in the spring, winter and fall afternoon hours is largely zero carbon and zero NOx, the afternoon and early night electrical generation supplying the electrical grid is anything but zero NOx. Until the electrical grid in Southern California is supplied solely by solar or other zero carbon means, zero emission water heating or steam production is a fallacy exactly counterintuitive to the proposed goals of the AQMD outlined in PAR 1146.2.
3. The PAR1146.2 staff report on **COST-EFFECTIVENESS** should include analysis of specific 1146.2 installations instead of fictional scenarios presented. 4-3
 - a. The **INCREMENTAL COST-EFFECTIVENESS of Electrical Panel Upgrade Cost** on Page 2-14 of the Staff Report “panel upgrade cost estimate of \$5,000”⁴ should be

¹ U.S.E.I.A

https://www.eia.gov/about/copyrights_reuse.php

² Preliminary Draft Staff Report PAR 1146.2 Presentation

<https://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/rule-1146-1146.1-and-1146.2/par-1146-2-preliminary-draft-staff-report-january-2024.pdf?sfvrsn=19>

³ Atmos

Zero, New Belgium Brewing

<https://www.craftbrewingbusiness.com/featured/new-belgium-brewing-continues-to-embrace-clean-tech-works-with-atmoszero-on-first-of-its-kind-electrified-boiler/>

⁴ Preliminary Draft Staff Report PAR 1146.2 (Pg. 2-14)

- reviewed and confirmed by a third party as it is far more likely to be the cost of getting an estimate for an electrical panel upgrade than the actual panel upgrade itself. A 600amp panel for the electrification of a 2mmbtu/hour steam boiler will be between \$50,000 to as much as \$200,000, depending on if there's utility service available AND the costs of the utility line/transformer upgrade. This possible deviation from 2022 AQMP estimates must be concretely falsified before any implementation of PAR 1146.2.
- b. The AQMD 2022 Air Quality Management Plan (Dec 2, 2022) states the following – page 8-17:
 - i. "...many buildings will likely need additional electrical panel upgrades and other infrastructure to support the increased electrical load needed to power the replacement appliances. These infrastructure upgrades can be far more costly than the cost of replacing gas appliances."⁵
 - c. PAR 1146.2 staff report fails to include the cost associated with utility charges for upgraded service. Assuming the local utility grid has capacity, the upgrade from the line transformer to the newly upgraded panel could be more than the newly powered equipment and the electrical panel upgrade combined.

Cont'd
4-3

- 4. Any **Incremental Cost Effectiveness Equation, Energy Input Method** must include theoretical Coefficient of Performance (COP).
 - a. The theoretical COP of a heat pump serves as a check of heat pump manufacturers advertised COP – as any advertised COP cannot exceed that of theoretical as dictated by the temperature of the cold and hot heat sinks. (The pilot study of AtmosZero COP of 329F steam given sub-zero heat supply cannot exceed 2.39)⁶
 - b. **Incremental Cost Effectiveness** calculation as presented in PAR 1146.2 is incomplete in that the stated COP relies solely on that provided by vendors rather than actual temperature and mass flow of all hot water and boiler demand scenarios.

4-4

Discussion:

4-5

California needs three times more power capacity to reach 100% clean energy by 2045. An initial analysis suggests the goal is technically feasible but only with a sustained high pace of construction: 6 GW annually for the next 25 years⁷. PAR 1146.2 imposes significant complications toward that goal as the electrification of 1146.2 sources adds to a significantly overloaded Southern California electric grid. Concurrently, the electrification of the transportation sector has exposed the severe shortage of electrical transmission.

<https://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/rule-1146-1146.1-and-1146.2/par-1146-2-preliminary-draft-staff-report-january-2024.pdf?sfvrsn=19>

⁵ The AQMD 2022 Air Quality Management Plan. Dec 2, 2022 (pg. 8-17)

<https://www.aqmd.gov/docs/default-source/clean-air-plans/air-quality-management-plans/2022-air-quality-management-plan/final-2022-aqmp/final-2022-aqmp.pdf?sfvrsn=16>

⁶ Ibid: AtmosZero, New Belgium Brewing

⁷ CalMatters Race to Zero (pt. 1)

<https://calmatters.org/environment/2023/01/california-electric-cars-grid/#:~:text=California's%20target%20to%20build%20at,gigawatt%20of%20wind%20per%20year.>

The requirement of electrifying 1146.2 sources is conceived in ignorance of the State's clean energy plan, in that the additional load on the grid falls within the same time frame where Southern California utilities grid demand approaches that of available supply⁸. The electrification of the heavy truck transportation sector alone doubles the existing grid demand of 60 gigawatts.

Cont'd
4-5

I recognize that the AQMD has no interest in facilitating the State's clean energy goals, however efforts to reduce NOx emissions via electrification of 1146.2 sources irrefutably depends on electricity being available and cheap, both of which are unreasonable assumptions.

Where does Electricity come from: As stated earlier, PAR1146.2 incorrectly assumes that the electrification of 1146.2 sources is zero carbon. Assuming the latest SCE electrical heat rate of 8000btu/kw-hr alongside the location of these incremental fossil fueled peaker plants within AQMD jurisdiction AND that such peaker plants have an emission rate of 2.5ppm corrected to 15% O₂, *the electrification mandated by PAR 1146.2 may actually increase basin NOx emissions.*

Conclusion:

Should the AQMD fail to consider these critical oversights and implement PAR1164.2 without significantly greater adherence to: 1) the reality of rapidly approaching grid overload in the State of California, 2) in-depth facility-level costs for Types 1 & 2 Boiler and Pool Heater electrification *beyond abstraction*, and 3) emissions sourcing and generation coincident to boiler and pool heater electrification on the scale of PAR 1146.2; electrical infrastructure, industrial function, carbon emissions and, most counterintuitively, *even the NOx emissions targeted by the proposed regulation* may be irreversibly worsened.

In support for the well-being of residents and businesses in southern and greater California AND our necessary commitment to reducing toxic and greenhouse gas emissions BAE implores that these comments be taken into consideration before implementation of the potentially harmful and dangerous PAR 1146.2.

RESPONSE TO COMMENT LETTER #4

Response to Comment 4-1:

Staff appreciates BAE's comments on PAR 1146.2. Staff recognizes the importance of electric grid reliability for electric units, but also for natural gas units, which often require electricity to operate. The CEC, CPUC, and CARB are working to coordinate efforts, identify issues not covered by ongoing efforts, and assess needed actions to better align the energy system with the state's climate targets. The CEC adopts an IEPR every two years and an update every other year, and the 2022 IEPR has recognized the proposed zero-emission requirements for residential and commercial buildings in California and included recommendations and updates to the energy demand forecast. Furthermore, CAISO is planning billions of dollars in transmission capacity projects over the next 20 years, and the 20-Year Transmission Outlook document from May 2022 considers transmission needs to meet load and renewable energy growth aligned with state policy. In 2021, the CPUC created new programs and modified existing programs to reduce energy demand and increase energy supply during critical hours of the day. Per Senate Bill 350 (De León, 2015), the CPUC developed an integrated resource planning process to ensure California's electric sector meets its greenhouse gas reduction goals while maintaining reliability at the lowest possible costs. On the utility level, according to SCE's 2021 Sustainability Report, SCE is expected to invest significantly in the electric grid, including energy storage. SCE also expected increases in Distributed Energy Resources such as solar.

There are products existing and emerging in the market that can meet the high-water temperature demand. For example, an internet search of examples of units sold or installed in U.S. or Southern California with focus on high water temperatures found products providing water temperature between 160- and 248-degrees Fahrenheit, with waste heat recycling systems capable of achieving up to 248 degrees Fahrenheit. Staff recognizes that for steam, heat pump technology may not be viable in the market yet, and for certain industrial processes, heat pump technology is not as mature. As part of the BARCT assessment, including discussions with manufacturers, staff determined that a temperature threshold was necessary to provide more time for the zero-emission technology market to mature for high temperature applications. As discussed above, zero-emission technologies for providing water temperatures up to 180 degrees Fahrenheit are available. Further discussion in a later section indicates that California Plumbing Code hot water temperature requirements are also up to 180 degrees Fahrenheit. Staff is proposing a temperature threshold of 180 degrees Fahrenheit for special consideration on high temperature applications with further implementation dates. Staff intends to conduct a status update /technology check-in prior to the proposed implementation dates for high temperature units to gather information on changes in technology development and availability.

Response to Comment 4-2:

Rule 1146.2 regulates the emission levels of the water heater, boiler, or process heaters themselves and does not include a lifecycle analysis of the emissions generated when producing the fuel needed to power the units. That is how BARCT assessments are conducted, and it is the same regardless of if the units are powered by natural gas, hydrogen, electricity, etc. Emissions generated during the production of natural gas,

hydrogen, or electricity are controlled by other South Coast AQMD regulations. The goal of the proposed amended rule is zero NO_x emissions at the unit level. Staff does not claim the generation of electricity produces zero NO_x emissions.

Please see Response to Comment PW-1 for more details on emissions from the electric and natural gas systems.

Response to Comment 4-3:

The cost-effectiveness analysis for PAR 1146.2 includes case studies recommended by manufacturers and installers. The capital costs were sourced from internet searches and manufacturer information, and more discussion on the data sources can be found in Chapter 2 of this staff report. The cost-effectiveness analysis relied on the panel upgrade cost estimate of \$5,000 from the 2022 AQMP and considered a unit age of 30 years for the panel. However, the cost of an electrical panel upgrade was adjusted to account for this longer unit age of the electrical panel versus the unit. For some categories involving residential units, the panel cost was split between residential appliances. Electrical panel upgrades will not be required for all instances where conventional units are replaced with zero-emission units, so staff assessed the cost-effectiveness with and without the estimated cost of the upgrades.

Staff consulted contractors for utility line/transformer upgrade and understands this type of upgrade may be required but is not commonly required. Upgrades on the utility side of the meter is utility company's responsibility, but consumers do bear most of the cost. PAR 1146.2 was updated to include alternative compliance options to address utility upgrade and emergency replacement concerns that allow additional time if needed. Staff will monitor the cost impact and include it in the status update/technology check-in by June 1, 2027.

In addition to options under Rule 1146.2, the South Coast AQMD has several NO_x rules for boilers and heaters, based on their rated heat input. Over the years, many facilities opted to install [many multiple](#) small water heaters or boilers subject to Rule 1146.2 for a variety of reasons including costs, flexibility, no permit requirements, etc. Facilities will maintain this flexibility and if the estimated cost of installing a zero-emission unit less than 2 MMBtu/hour is too high, the facility can opt to install a larger unit regulated by Rule 1146 or Rule 1146.1 that allows for low-NO_x units that would not require a utility upgrade. Those rules have lower NO_x limits than Rule 1146.2 so emission reductions would still be achieved if facilities opted for that approach, though it would be speculative to estimate the emissions impact on such business decisions.

Response to Comment 4-4:

Staff acknowledges that the heat pump product energy efficiency measure, COP, is an industry standard, and that the COP of heat pump products varies between 3.0 and 6.0 or more depending on the product. There will be case-by-case differences between different

installations. For the analysis, staff made assumptions, disclosed those assumptions, discussed them in public meetings, and sought and considered stakeholder input.

Response to Comment 4-5:

Regarding electric grid capacity and supply, please see Response to Comment 4-1 which provides staff response to a similar comment and Chapter 2 in this staff report for further discussion.

Regarding the lifecycle emissions from electric generation, please see Response to Comment PW-1. Nevertheless, staff has reviewed the calculations provided by the commenter through email communication and recognizes that several inaccurate assumptions were made by the commenter: a lower NOx emission by gas-fired units (10 ppm) than the current Rule 1146.2 limit (20 ppm); that 100 percent of electricity comes from natural gas power plants using the highest emission limit, when 24.7 percent of electricity in SCE comes from natural gas; that an electric boiler would replace the gas-fired unit, rather than a heat pump which is at least three times more efficient. The lifecycle emission should be much lower than the commenter's estimate.

COMMENT LETTER #5

From: Brian <brian@calhot.com>
Sent: Monday, February 19, 2024 12:51 PM
To: Heather Farr <hfarr@aqmd.gov>
Subject: [EXTERNAL] Rule 1146.2 proposed changes

I understand the want for new buildings to be equipped with heat pumps. Retrofitting an existing building is going to be a bigger endeavor than you may think. In Rule 1146.2 when changing out the standard atmospheric equipment for Low NOx equipment you were changing a gas box that used the same power requirements for another box that was about a foot longer and the storage tank stayed the same size. In changing a gas water heater to heat pump that box is being replaced by a number of slightly smaller boxes. That is not the problem, the amount of storage required for the heat pumps is the problem. 5-1

The roof or the building was designed for 500 gallons of water now has to be upgraded to handle 2,000 to 4,000 gallons of water. The structural for the roof in most apartment buildings will need to be reinforced to handle the additional weight of the storage tanks and the water they hold. 5-2

The power to the building will need to be upgraded to handle the current that the heat pumps require. Again you are not changing out one or two boxes for the gas box that uses 120V you are going to need to supply 240V to 10 or more units. The line entering the building is about as thick as your thumb for the gas, the power wires needed to enter the building will need to be about as thick as your wrist. This upgrade in power will be expensive, some of it will have to wait as the power grid in the area is upgraded to supply the needed power. Until the power company has the infrastructure to power the heat pumps, your rule can not be enacted. 5-3

For buildings that have the equipment rooms inside the building, the boilers use one square inch for every 4,000 BTUs of fresh air for combustion and for ventilation. A million BTU boiler will need two screened opening to the room two (2) feet by two (2) feet. Each heat pump will need an opening about five (5) feet by eight (8) feet and to replace the million BTU heater you will need about eight (8) of the units. 5-4

Most installations are going to close the business for a time, my guess is 3 to 9 months to do the upgrades and set up the equipment. In the case of a Hotel, Motel, Restaurant, coin laundry, and apartment complex they will need to close. Many of the companies will not be able to afford the millions of dollars required in your change out to handle the added weights and power requirements of the equipment. 5-5

For apartment dwellers, they will need to move out and find another place to live, the good news is that in LA that landlord has to pay each lease \$12,000 to move. Rents will increase, to pay for the moving costs, the lost rents while the building is retrofitted, and the cost of the equipment and labor to do the work. Condo owners will have to move out, pay mortgage, pay rent, and pay their part in the cost of the equipment and upgrades to make the equipment work.

With the replacement of Gas BTU to Electric KW we are going to need to add about 293 KW for each Million BTUs you eliminate. We don't have the power production capacity to meet the needs. Before you say renewable sources, they turned off all fossil fueled sources and we had less than 7 minutes of renewable power. It was actually around 5 seconds but I am guessing that after a year it may have increased up to 40% new sources. There was talk about building a power plant in Arizona to power Los Angeles. But what would stop that local Air Quality Board from passing a rule that forbids plants that export power or taxes / fines them excessively? Is the SCAQMD going to allow new gas powered power plants in the SCAQMD area? Other wise we are going to have to ration power. Only charge your electric car on even or odd days according to your address?

5-6

We sell Heat Pumps. But as I said the problem is three fold, not sufficient power or infrastructure, the amount of water and the weight needed for a heat pump to work, and the closing of businesses and residents to make the switch from BTU to KW that will result in an increase in the costs of Housing, lodging, food, laundry, and as those go up associated business will raise their prices.

RESPONSE TO COMMENT LETTER #5**Response to Comment 5-1:**

Staff appreciates the comments on PAR 1146.2. Regarding the required space for zero-emission equipment, please refer to Response to Comment PW-2.

Response to Comment 5-2:

Staff recognizes that there may be some roof installations, and that there may be options for installations in other locations for those cases. Staff also acknowledges that some stakeholder's case studies have oversized the heat pump replacement, overestimating the number or the capacity of heat pumps and storage tanks, thus taking up more space. For oversized units and the need for multiple units, facilities have the ability to install a larger unit that complies with Rules 1146 and 1146.1. For a further discussion, please see Response to Comment 4-3.

Response to Comment 5-3:

Regarding electrical upgrade and associated cost impact, please see Response to Comment 4-3. Existing buildings may have more challenges than new buildings to replace gas-fired units, so staff included alternative compliance options to address utility upgrade and emergency replacement concerns and later implementation dates to give more time for units in existing buildings to be replaced. In addition, staff included an additional 20 percent to the cost of each unit to address installation and other potential additional costs. As stated in Chapter 2 of this staff report, for some units this may be an overestimate, for some it may be an underestimate so applying the additional costs to all units, estimated to be approximately 1.07 million units, is a conservative assumption. Further, as heat pump installations become more commercially available and common, the installation costs are anticipated to be comparable to installation costs for conventional units. In addition, staff included costs for electrical panel upgrades. Staff will evaluate the electrical upgrade and associated cost impact and include it in the status update/technology check-in by June 1, 2027.

Response to Comment 5-4:

Please see Response to Comment 5-1.

Response to Comment 5-5:

Staff understands the concern and added paragraph (i)(4) to provide an alternative compliance option for emergency replacement when an electrical upgrade for more power supply capacity is required to comply with zero-emission limits. This allows the use of a temporary unit that complies with Table 1 emission limits (20 ppmv NOx/400 ppmv CO) for up to six months. Staff visited several commercial locations, and more details are included in Response to Comment 1-1. Staff discussed the installation efforts with the

commercial businesses and stakeholders and have not heard of any facility shutdowns required.

Staff gathered cost data for various types of units for the cost-effectiveness analysis described in Chapter 2 of this report. Heat pumps are the primary zero-emission technology. The analysis accounted for higher equipment and installation cost, operational cost of switching from gas to electricity, and electrical upgrade cost for some cases. Although the analysis determined that it is cost-effective for most of the equipment categories to implement zero-emission, staff understands the challenge of higher upfront costs. Staff also recognizes that many residents live in tenant-occupied multifamily homes, and that increases in rent may be attributed to factors other than zero-emission water heater replacements. Staff also recognizes that PAR 1146.2 would require unit replacement at end of unit age, which means that the analysis should consider incremental cost. Staff is developing a rebate program to help lower the cost for some consumers and centralizing information for incentive and financing opportunities offered by other agencies and organizations. Further, as zero-emission technologies become more mature and more widely adopted in the market in the future, there will be less cost impact.

Response to Comment 5-6:

Staff recognizes the importance of electric grid reliability for electric units, but also for natural gas units, which often require electricity to operate. The CEC, CPUC, and CARB are working to coordinate across efforts, identify issues not covered by ongoing efforts, and assess needed actions to better align the energy system with the state's climate targets. The CEC adopts an IEPR every two years and an update every other year, and the 2022 IEPR has recognized the proposed zero-emission requirements for residential and commercial buildings in California and included recommendations and updates to the energy demand forecast. Furthermore, CAISO is planning billions in dollars in transmission capacity projects over the next 20 years, and the 20-Year Transmission Outlook document from May 2022 considers transmission needs to meet load and renewable energy growth aligned with state policy. In 2021, the CPUC created new programs and modified existing programs to reduce energy demand and increase energy supply during critical hours of the day. Per Senate Bill 350 (De León, 2015), the CPUC developed an integrated resource planning process to ensure that California's electric sector meets its greenhouse gas reduction goals while maintaining reliability at the lowest possible costs. On the utility level, according to SCE's 2021 Sustainability Report, SCE is expected to invest significantly in the electric grid, including energy storage. SCE also expected increases in Distributed Energy Resources such as solar. In 2021, according to the CEC, renewable generation accounted for 33.6 percent of the total California Power Mix, not including solar photovoltaic systems installed on residential and commercial buildings that are less than one MW as they are typically considered distributed generation and not required to report to CEC. The California Power Mix is the percentage of specified fuel types derived from the California Energy Mix, and the California Energy Mix is the total in-state electric generation plus energy imports. There is expected to be more renewables adoption by states in the future, and California Senate Bill 100 called for a Renewables Portfolio Standard of 60 percent by 2030. Electricity imports account for

approximately 30 percent of total system electric generation, with other states pursuing Renewable Portfolio Standards and state energy goals.

Subject: [EXTERNAL] Proposed Amended Rule 1146.2 comments

Hi!

Hope you're doing well. I just wanted to send a comment in regards to the proposal amended rule for 11 46.2. This rule would have a detrimental impact to our business as the cost of replacing our current equipment would be financially unsustainable, and would possibly cause us to close our doors. Please take into consideration the smaller businesses when proposing such a widespread change . 6-1

A major concern of mine is not only the price of the equipment, but the cost of operations. As well as the impact this will have on the electrical grid. We are already facing power, shut, offs, and possible rolling blackouts in during the summer and winter months. Such shut off, would be catastrophic to our business if we become reliant entirely on electricity.

Thank you ,
Anna
Sent from my iPhone

RESPONSE TO COMMENT LETTER #6

Response to Comment 6-1:

Staff appreciates the comment on PAR 1146.2 and recognizes the concerns of small businesses. Staff gathered cost data for various types of units for the cost-effectiveness analysis described in Chapter 2 of this report. Heat pumps are the primary zero-emission technology. The analysis has accounted for higher equipment and installation costs, operational cost of switching from gas to electricity, and electrical upgrade cost for some cases. Although the analysis determined that it is cost-effective for most of the equipment categories to implement zero-emission, staff understands the challenge of higher upfront costs. Staff is in the process of developing a rebate program to help lower the cost for some consumers and centralizing information for incentive and financing opportunities offered by other agencies and organizations. There are some federal and state incentives for zero-emission commercial appliances including Section 179D of the Internal Revenue Code, which allows deductions for energy-efficient commercial buildings, including new or existing buildings.⁶⁸ The Inflation Reduction Act extended and expanded these tax deductions.⁶⁹ TECH Clean California launched more state-wide incentives for multifamily and commercial water heating in 2023.⁷⁰ There are also utility incentives for appliances in commercial buildings, including SCE's Willdan Commercial Energy Efficiency Program, which incentivizes replacement of an existing electric resistance or gas-fired water heater with a packaged heat pump water heater.⁷¹ GoGreen Financing also provides loan financing options.⁷² Further, as zero-emission technologies become more mature and more widely adopted in the market in the future, there will be less cost impact. To address further concerns, PAR 1146.2 provides alternative compliance options to address specific concerns including emergency replacement, utility upgrades, construction, replacement of more than four units with in-the-same consecutive compliance years, properties under lease, and other cases. There is also an exemption for small businesses from the unit age requirement, so that small businesses are not subject to the zero-emission requirements at the end of unit age. They can operate their equipment beyond the unit age, replace them at natural turn-over or break down, and are subject to zero-emission requirements if the replacement is on and after Table 3 zero-emission compliance dates.

Regarding electric grid reliability, please refer to Response to Comment 4-1.

Emily Yen
Planning, Rule Development, and Implementation
South Coast Air Quality Management District (SCAQMD)
21865 Copley Drive, Diamond Bar, CA 91765
(Submitted via email to: eyen@aqmd.gov)

Re: Proposed Amended Rule 1146.2. Emissions of Oxides of Nitrogen from Large Water Heaters and Small Boilers and Process Heaters

Dear Ms. Yen:

AHRI appreciates the opportunity to submit comments on SCAQMD's updated Proposed Amended Rule 1146.2 (PAR 1146.2) regarding "Emissions of Oxides of Nitrogen from Large Water Heaters and Small Boilers and Process Heaters" posted to AQMD's docket on February 20, 2024¹.

Background on AHRI

AHRI represents more than 330 manufacturers of heating, ventilation, air conditioning, commercial refrigeration (HVACR) and water heating equipment. It is an internationally recognized advocate for the HVACR and water heating industry and certifies the performance of many of the products manufactured by its members. In North America, the annual economic activity resulting from the HVACR industry is more than \$211 billion. In the United States alone, AHRI member companies, along with distributors, contractors, and technicians employ more than 704,000 people.

Introduction

AHRI and its members have reviewed the updated PAR 1146.2 and understand that its purpose is to obtain further NO_x emission reductions and to implement the 2022 Air Quality Management Plan (AQMP) Control Measure C-CMB-01-Emission Reductions from Replacement with Zero

¹ Proposed Amended Rule 1146.2 (aqmd.gov); <https://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/rule-1146-1146.1-and-1146.2/par-1146-2-draft-rule-language-february-2024.pdf?sfvrsn=6>.

Emission or Low NOx Appliances – Commercial Water Heating (Control Measure C-CMB-01).

AHRI and its members support many of the changes in the updated PAR 1146.2. However, AHRI and its members have additional concerns and request that SCAQMD consider our comments herein.

General Comments

1. BARCT Assessment

7-1

AHRI and its members understand that the purpose of a BARCT assessment is to establish emission limits for specific equipment categories consistent with state law and is defined as: “an emission limitation that is based on the maximum degree of reduction achievable, taking into account environmental, energy, and economic impacts by each class or category of source.”² AHRI and its members have the following comments with regards to several steps in this approach.

a. Equipment Categories

In the Preliminary Draft Staff Report PAR 1146. 2³ (Staff Report), Table 2-1, the “Type 1 High Temperature Unit” refers to “Type 1 units that are high temperature units, which are units used to produce steam or to heat water above 190 degrees Fahrenheit.” AHRI and its members are pleased to see that in the updated PAR 1146.2, SCAQMD has now set the limit at 180 degrees Fahrenheit for water heaters.

While AHRI and its members would prefer the clarity given in the Working Group 4 proposal, which highlighted boilers and process heaters instead of “High Temperature Units,” we support the compromise decision to adopt a limit of 180 degrees rather than 190 degrees. This decision will align the PAR with the American Society of Mechanical Engineers (ASME) thresholds that impact storage water heaters, which is 180°F.⁴ Therefore, while aligning to DOE classifications for boilers and process heaters is preferred, it is more reasonable to define the limit at 180 degrees instead of 190 degrees as it will harmonize with existing standards.

AHRI and its members appreciate that SCAQMD staff “intends to conduct a technology assessment prior to the proposed implementation dates for high temperature units to gather information on changes in technology development

² CA Health and Safety Code Section 40406.

³ <https://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/rule-1146-1146.1-and-1146.2/par-1146-2-preliminary-draft-staff-report-january-2024.pdf?sfvrsn=19>; <https://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/rule-1146-1146.1-and-1146.2/par-1146-2-preliminary-draft-staff-report-january-2024.pdf?sfvrsn=19>.

⁴ <https://www.asme.org/codes-standards>.

and availability”⁵ as this endeavor will be instrumental in ensuring that key technologies required to carry out this rule are both commercially available and economically justified. AHRI looks forward to participating in those discussions. Additionally, AHRI and its members support the proposal to bifurcate the instantaneous water heater category. The bifurcation of this product class brings this PAR into alignment with the U.S. Department of Energy (DOE) classification of the residential and commercial sizes of these products. Alignment of state regulations with federal product classifications is paramount to reducing regulatory burden as manufacturers design and build their products based off the DOE classification.

Cont'd
7-1

b. Economic Impacts

The BARCT assessment must also look at economic impacts and the Staff Report states that “major components of the cost-effectiveness analysis are capital costs, emission reductions, discount rate, and equipment useful age” and provides equations to explain its reasoning. However, AHRI members have questions and concerns about this approach.

Although AHRI and its members recognize and appreciate that SCAQMD staff make extensive changes in this area in the updated PAR 1146.2, we still have concerns about whether the Cost Effectiveness Analysis provides a proper threshold and whether it provides sufficient transparency in its data sources or cost justifications.

Furthermore, SCAQMD has created a “cost-effectiveness screening threshold” that essentially has no enforcement mechanism (please also see our comments in the “Screening Threshold” section below).

2. Support for Exemptions

7-2

AHRI and its members are pleased to see that SCAQMD restored the Low Use Exemption in the updated PAR 1146.2. We believe this is important because the underlying issue allows for the use of emergency backup. For example, during a power outage, gas equipment could run on a generator backup, but it is unlikely any heat pump or electric resistance equipment could. We have not yet, however, had an opportunity to evaluate other updates in this section, such as the change from 9000 therms to 3000 therms. Therefore, AHRI and its members support this but acknowledge that certain aspects of the new proposals may need further consideration or refinement. Additionally, AHRI is supportive of SCAQMD creating an exemption acknowledging the difficulties surrounding mobile homes. We acknowledge that this conversation stemmed out of the working group meetings for PAR 1111/1121⁶ for furnaces and water heaters and hope that this exemption is carried through in that PAR as well.

⁵ <https://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/rule-1146-1146.1-and-1146.2/par-1146-2-preliminary-draft-staff-report-january-2024.pdf?sfvrsn=19>; <https://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/rule-1146-1146.1-and-1146.2/par-1146-2-preliminary-draft-staff-report-january-2024.pdf?sfvrsn=19>.

⁶ Control of Nitrogen Oxides from Residential Type, Natural Gas-Fired Water Heaters.

3. Support for Harmonization with Other Agencies

7-3

To avoid adding unnecessary extra burden on manufacturers, AHRI and its members applaud SCAQMD's efforts to align compliance dates with other agencies such as the California Energy Commission (CEC) and the Department of Energy (DOE) in its updated PAR 1146.2 and ask that the agency continue this effort wherever feasible. For example, AHRI appreciates that SCAQMD aligns its phase 1 new construction timelines with CEC Title 24 Energy Code cycles. The 2025 CEC Energy Code is currently under development and is expected to be adopted by January 1, 2025. The code is not expected to take effect until January 1, 2026. The 2025 version of Title 24 will have a large emphasis on heat pump so alignment with the code provides a cohesive effective date for the market to transition over.

SCAQMD should align with state energy code cycles and Department of Energy (DOE) rulemakings. AHRI and its members also recommend keeping the proposed four-year gap between new construction and existing construction compliance dates.

4. Screening Threshold

7-4

SCAQMD has created a "cost-effectiveness screening threshold" that essentially has no enforcement mechanism. The staff report states that,

The 2022 AQMP established a cost-effectiveness screening threshold of \$325,000 per ton of NO_x reduced based on 2021 dollars. The 2022 AQMP stated that this screening threshold will be adjusted based on the annual California Consumer Price Index (CPI). PAR 1146.2 currently considers a \$349,000 per ton of NO_x reduced cost-effectiveness screening threshold using 2022 dollar-figures. The 2022 AQMP threshold is neither considered a starting point for control costs, nor an absolute cap.⁷

AHRI and its members also recommend that SCAQMD enforce this limit as a cap. We also recommend that the cost-effectiveness calculations be done without any TECH Clean California incentives.⁸

5. Labeling Requirement

7-5

The updated PAR 1146.2 SCAQMD is proposing a labeling requirement under the new Subdivision (j) for the period between the new building compliance date and the existing building compliance date of an equipment category. AHRI and its members do not support this proposal.

⁷ <https://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/rule-1146-1146.1-and-1146.2/par-1146-2-preliminary-draft-staff-report-january-2024.pdf?sfvrsn=19>.

⁸ <https://techcleanca.com/>.

This information is already available to building inspectors and managers in several forms. SCAQMD currently operates a compliance database with product listings for all compliant products, the acceptable installation cases can be added to that database with limited impact to manufacturers production lines.⁹

Cont'd
7-5

Furthermore, given that a 0 NOx limit would effectively ban gas installation, inspectors can easily verify compliance simply by confirming the fuel source of the appliance without the need for labels.

Lastly, in reference to PAR 1146.2, Subdivision (j)(1) "Labeling and Reporting Requirement," Table 4, (below) AHRI and its members do not understand the rationale for requiring units shipped prior to all Table 3 compliance dates to be marked "For Installation and Use in Existing Buildings Only." We would expect this marking to be applicable to units supplied or offered for sale on or after the start date and before the end dates in Table 4.

PAR 1146.2, Subdivision (j)(1) Labeling and Reporting Requirement, Table 4 – Labeling Schedule

Unit's Compliance Schedule	Labeling Requirements	
	Start Date	End Date
Phase I	January 1, 2026	January 1, 2029
Phase II	January 1, 2028	January 1, 2031
Phase III	January 1, 2029	January 1, 2033

For these reasons, we ask SCAQMD to remove this labeling requirement proposal, as it is unnecessary and would be expensive and burdensome for manufacturers.

6. Alternate Compliance Pathways

7-6

AHRI supports SCAQMD's addition of the Section (i) for Alternative Compliance Options. The addition of a section to account for delays caused by utilities will be instrumental in ensuring a smooth transition to 0 NOx without affecting services to a building. However, given that this rule will be phasing out the ability to sell these products into the district, AHRI would recommend that SCAQMD staff review and understand what the availability of ultra-low NOx gas fired products will be in the state that can be used as a temporary unit while a building is awaiting a service upgrade. While there could be options available at the onset of this rule, in 15-25 years, the available stock may be limited when the last of these products are being transitioned.

7. Need for Broader Stakeholder Engagement

7-7

While we appreciate SCAQMD's stakeholder engagement efforts, we urge the agency to

⁹ <https://www.aqmd.gov/home/rules-compliance/rules/support-documents/rule-1146-2-details>

continue to work with key affected sectors of the regulated community including engagement with installers and end users such as building owners to ensure any unknown issues or consequences are identified.

Cont'd
7-7

Conclusion

AHRI and its members appreciate SCAQMD's stakeholder engagement efforts towards this goal and have been attending meetings and workshops. AHRI and its members additionally look forward to collaborating with SCAQMD to achieve policy solutions that are practical, economical, and technologically feasible.

Thank you for allowing us to provide comments to SCAQMD on the updated Proposed Amended Rule 1146.2 regarding "Emissions of Oxides of Nitrogen from Large Water Heaters and Small Boilers and Process Heaters."

Please feel free to contact us directly if you have questions or need additional information.

Sincerely,

Stacy Tatman, MS, JD
AHRI Senior Director, Regulatory Affairs
Email: statman@ahrinet.org

RESPONSE TO COMMENT LETTER #7

Response to Comment 7-1:

Staff appreciates AHRI's comment on PAR 1146.2. Staff is proposing a temperature threshold of 180 degrees Fahrenheit for special consideration on high temperature applications with further implementation dates. Staff intends to conduct a technology assessment prior to the proposed implementation dates for high temperature units to gather information on changes in technology development and availability. Staff has also separated instantaneous water heaters into two categories by rated heat input capacities and appreciates the comment on this subject.

Staff gathered cost data for various types of units for the cost-effectiveness analysis described in Chapter 2 of this report, which were discussed with the Working Group throughout the rule development process. The analysis accounted for higher equipment and installation costs, operational cost of switching from gas to electricity, and electrical upgrade cost. Although the analysis determined that it is cost-effective for most of the equipment categories to implement zero-emission, staff understands the challenge of higher upfront costs. During the rule development process, staff strives to maximize emission reductions while considering cost-effectiveness. The cost-effectiveness threshold is neither considered a starting point or absolute cap for control costs, nor an enforcement tool. Instead, it provides a guide during rule development to identify cost-effective control options to present to the Governing Board for consideration during the Public Hearing. Staff is committed to identifying and proposing the cost-effective control options, but this cannot be done at the expense of foregoing emission reductions necessary for regional air quality attainment, especially given the magnitude of the emission reductions needed to meet the ozone standards.

Response to Comment 7-2:

Staff recognizes the importance of electric grid reliability for electric units, but also for natural gas units, which often require electricity to operate. The proposed new low-use exemption could be a transitional option for the implementation of zero-emission. Since the Public Consultation Meeting, staff has refined the proposal and divided the low-use threshold to two tiers based on unit size. Regarding zero-emission implementation in existing mobile homes, the proposed alternative compliance option is to provide more time for mobile home with instantaneous water heaters, during which time a natural gas fired instantaneous water heaters meeting the Table 2 emission limits can be installed.

Response to Comment 7-3:

Staff agreed with the commenter and extended the Phase I compliance date for new buildings by one year, from 2025 to 2026, to better align with the CEC Building Code effective date. Staff does not see a compelling reason to extend existing building compliance dates to keep the initially proposed four-year gap between new and existing building compliance dates.

Response to Comment 7-4:

Health and Safety Code 40920.6 requires the South Coast AQMD to consider cost-effectiveness as a factor in the rule process to adopt a control option as BARCT. The 2022 AQMP cost-effectiveness threshold provides a guide or reference for the cost-effectiveness analysis, which staff and the Governing Board consider when proposing and adopting BARCT emission limits. The cost-effectiveness threshold is not a hard cap and is not intended as an enforcement mechanism. Staff is committed to identifying and proposing cost-effective control/compliance options, while striving to achieve the emission reductions necessary for regional air quality attainment, especially given the magnitude of the emission reductions needed to meet the ozone standards. Cost-effectiveness is an important basis for the proposed implementation schedule. PAR 1146.2 proposes a later implementation for equipment categories that are less cost-effective.

Staff presented various incentive and financing opportunities (e.g., TECH Clean California incentives) that could lower the costs. However, for the cost-effectiveness calculations, staff did not include the incentives to mitigate the costs.

Response to Comment 7-5:

PAR 1146.2 is proposing a labeling requirement under the new subdivision (j) for the period when a gas unit can be installed in some applications and not in others. Table 4 start dates are the zero-emission implementation dates for installations in new buildings, and Table 4 end dates are the zero-emission implementation dates for installations in existing buildings. The period between start and end dates is when gas units can be installed in existing buildings but not in new buildings, which is the message the required label pursuant to paragraph (j)(1) would convey. Paragraph (j)(2) requires labeling for instantaneous water heaters rated less than or equal to 200 kBtu/hr installed in mobile homes during the period when natural gas fired instantaneous water heaters can replace the existing instantaneous water heaters in mobile homes but cannot be installed in other applications. Labeling requirements were previously proposed during the rulemaking process and then removed after stakeholder meetings. However, concerns were raised over enforcement during these in-between periods in the absence of labeling. Staff recognizes the need for labeling requirements to differentiate the units allowed to be installed in new and existing buildings. Please also see Response to Comment PC-9 for more details.

Response to Comment 7-6:

Staff recognizes the need to provide additional time for emergency replacements prior to future effective dates or when utility upgrades are needed outside of the facility's reasonable control. The proposed alternative compliance options and exemption provisions will allow limited use of gas units. The demand for these temporary units could be met by a robust rental marketplace; a rental unit market exists today and could expand to meet future demand, and scaled back as the transition to zero-emission units nears completion.

Response to Comment 7-7:

PAR 1146.2 was developed through a public process that began with the development of the 2022 AQMP and was re-initiated during the second quarter of 2023. The public process

included a series of working group meetings, a public workshop, and a public consultation meeting. In addition, staff held numerous individual meetings with stakeholders who may be impacted by this rulemaking and conducted multiple site visits to various stakeholders. Staff continues to be open to stakeholder feedback and input during the rulemaking process.

COMMENT LETTER #8

March 4, 2024

Via Email: eyen@aqmd.gov

Ms. Emily Yen
Planning, Rule Development, and Implementation
South Coast Air Quality Management District
21865 Copley Drive, Diamond Bar, CA 91765

RE: Proposed Amended Rule 1146.2 – Control of Oxides of Nitrogen from Large Water Heaters, Small Boilers, and Process Heaters

Dear Ms. Yen:

Rheem Manufacturing Company (Rheem) appreciates the opportunity to submit the following comments in response to the South Coast Air Quality Management District's (SCAQMD) Proposed Amended Rule 1146.2 – Control of Oxides of Nitrogen from Large Water Heaters, Small Boilers, and Process Heaters (Proposed Rule).

Rheem is an industry leader in total heating, cooling, refrigeration and water heating solutions and one of the few global brands with product offerings covering residential and commercial heating, cooling, conventional and hybrid storage water heaters (HPWH), tankless water heaters, solar water heating systems, pool and spa heaters, commercial boilers, residential hydronic and geothermal systems, commercial refrigeration products, indoor air quality accessories, and replacement parts for all categories. Rheem is headquartered in Atlanta, Georgia, and has U.S. based manufacturing facilities in Alabama, Arkansas, California, Connecticut, and North Carolina. The company also operates distribution facilities throughout the US, Canada, and many other countries around the world. Rheem manufactures commercial boilers and pool heating equipment at the Raypak facility in Oxnard, CA, both equipment types are affected by this Proposed Rule.

Rheem appreciates SCAQMD staff's efforts to update Rule 1146.2, and specifically to include and consider stakeholder input. To that end, we are pleased to see improvements in the latest Proposed Rule language that address many concerns raised during the last working group meeting. Rheem would like to affirm the latest changes and reiterate our concerns around the compliance dates and the newly added labeling and reporting requirements.

Definitions

Rheem supports the updated definitions of high temperature unit, instantaneous water heater, mobile home, and new building.

8-1

Building Type

Rheem recommends aligning the residential and multifamily structure definitions with California's Building Code (Title 24).¹ Title 24 exhaustively lists the building types in their "Residential Building" and "Multifamily Building" definitions, while also excluding certain types of dwellings that are for commercial purposes, such as hotels. Rheem notes that under the proposed definitions a hotel could be considered a dwelling for more than four families and fall under the multifamily structure definition.

High Temperature

Rheem appreciates SCAQMD amending the definitions of "high temperature unit" to include "designed" instead of "used" and 180°F instead of 190°F. These changes align with the historic understanding of high temperature applications and ease certification and compliance burden as the requirements will be around the unit and not the specific installed application.

It is becoming more well understood that electrification is only viable when there are heat pump solutions to an application.² Rheem notes that most heat pump water heaters can provide temperatures up to 140°F, with some capable of up to 160°F. Select heat pumps with higher temperature capability, have been identified, yet their market availability and suitability to replace existing equipment has not been reviewed. Also, it is not clear how much of the higher temperature rise is achieved with built-in electric resistance heating.

The US DOE definition of a "Residential-Duty Commercial Water Heater" includes, "Is not designed to provide outlet hot water at temperatures greater than 180 °F." Therefore, the US DOE has set >180°F as the starting point for commercial high temperature operation (where there is no longer a residential application) for water heaters. Above 180°F is also referenced throughout the ASHRAE Handbook as the recommended temperature for many applications such as sanitation, commercial kitchen, and laundry. Greater than 190°F is more typical of boiler applications. Many gas-fired water heaters and boilers operate within the 180-190°F range and, if the 190°F threshold was maintained, some of this equipment will likely be replaced with gas-fired equipment that can operate above 190°F, while other applications may not have viable solutions.

Finally, Rheem recommends added language to the rule to clarify how the high temperature qualification will be determined. More specifically, we recommend that a manufacturers declaration be used, with supporting certification standards documents to demonstrate high temperature operations.

¹ See Section 100.1 of TITLE 24, PART 6, BUILDING ENERGY EFFICIENCY STANDARDS FOR RESIDENTIAL AND NONRESIDENTIAL BUILDINGS.

² Electric resistance equipment uses much more electricity than heat pump equipment, which significantly increases emissions at the source. Even as more renewables come online, if significantly more capacity is needed due to electric resistance equipment the non-renewable electrical generation will continue to be needed.

Compliance dates

8-2

Rheem appreciates SCAQMD amending the January 1, 2025 compliance date; however, Rheem recommends SCAQMD either include an exemption for buildings constructed under permits obtained under the 2022 code or set a January 1, 2027, date as new construction permitted under the 2022 code can be initiated up to 12 months after the permit issue date (with 180-day extensions allowed).³ In addition, a later date would align more closely with the Bay Area AQMD zero emission date for this range of equipment.

Rheem also recommends that SCAQMD divide Type 2 units into above and below 1 MMBtu/h and set the greater than 1 MMBtu/h category as Phase III. Heating capacities greater than 1 MMBtu/h are significantly more difficult to produce with heat pump technology.

Labeling and Reporting

8-3

Rheem does not support the labeling and annual reporting requirements in section (j). Region-specific labeling adds significant complexity to the supply chain. Further, Rheem typically only has visibility to the first step in the distribution channel and has no clear way of determining where a unit is installed. This reporting requirement should be limited to distributors, retailers, and resellers operating within the South Coast region.

Exemptions

8-4

Rheem supports the exemption for "low usage" as described in sections (k)(2-3). However, Rheem recommends that the therms per year in section (k)(3) (*i.e.*, 3,000 therms) be scaled to the equipment input rate. For example, SCAQMD could determine a representative value of annual operating hours⁴ at full firing rate.

Thank you for the opportunity to provide these comments. If there are questions, please contact me directly.

Sincerely,

James Phillips
Senior Regulatory Affairs Manager
Rheem Manufacturing Company

cc: Karen Meyers, Joe Boros

³ See section 105.5.1 of the California Building Code: <https://codes.iccsafe.org/content/CABC2022P3/chapter-1-scope-and-administration>.

⁴ The operating hours could be based on 1) the expected downtime to replace or repair the primary zero NOx equipment that has failed or 2) the heating degree days for the region above which the zero NOx equipment has trouble meeting the load.

INTEGRATED HOME COMFORT

RESPONSE TO COMMENT LETTER #8

Response to Comment 8-1:

Staff appreciates Rheem's comment on PAR 1146.2. The proposed amended rule defines a Residential Structure as, "any structure which is designed exclusively as a dwelling for not more than four families, and where such equipment is used by the owner or occupant of such a dwelling. Residential Structures includes any structures on the property such as sheds and detached garages and appurtenances such as pools and spas."

Staff does not consider a hotel to be a multifamily building. Although the proposed amended rule language does not define hotels or multifamily structures, units subject to Rule 1146.2, e.g., water heaters, boilers, and process heaters fired with, or is designed to be fired with, natural gas that have a rated heat input capacity less than or equal to 2 MMBtu/hr, that are operated at a hotel or multifamily structure are subject to the rule. Moreover, there is no requirement proposed for units operated at hotel or multifamily buildings that differentiates them from units operated at other commercial buildings; therefore, there is no need for a multifamily or hotel definition in PAR 1146.2.

There are products existing and emerging in the market that can meet the high-water temperature demand. For example, an internet search of examples of units sold or installed in U.S. or Southern California with focus on high water temperatures found products providing water temperature between 160- and 248-degrees Fahrenheit, with waste heat recycling systems capable of achieving up to 248 degrees Fahrenheit. Chapter 2 of this report provides further detail on high temperature applications. Response to Comment PW-5 provides further detail on the temperature threshold. Staff intends to conduct a technology assessment prior to the proposed implementation dates for high temperature units to gather information on changes in technology development and availability.

High Temperature Unit is defined in the proposed amended rule language and described in the staff report. The rule's intent is to ensure high temperature units are installed for high temperature use. Only specifying units designed for high temperature can create rule circumvention. For example, a boiler is designed for high temperatures, but it could be used for comfort air or hot water with output water temperature less than 180 degrees Fahrenheit. For clarity, staff suggests the definition of "high temperature unit" shall specify that the unit is designed and used to produce steam or to heat water above 180 degrees Fahrenheit.

Response to Comment 8-2:

As the South Coast Air Basin has been classified as "extreme" nonattainment for the 2015 ozone standard, staff is required to consider emission reduction for all categories and set future effective dates to reduce emissions as early as feasible. Staff does consider other agencies' plans and rulemakings for alignment where appropriate but does not use a later implementation date set by another air district as the justification for pushing back proposed compliance dates for the South Coast Air Basin. PAR 1146.2 proposes earlier implementation dates for some equipment categories and later implementation dates for others based on the BARCT assessment.

Staff also considers that South Coast AQMD standards cannot be less stringent than the state-wide standard which will be set by CARB during its ongoing rulemaking process for zero-emission standards for space and water heaters sold in California with potential implementation in 2030. Staff believes that alignment with the Title 24 implementation date of January 1, 2026, for new buildings is feasible for the categories of units in Phase I of the compliance schedule.

Staff understands that Type 2 units that are not high temperature units or instantaneous water heaters may require more time for the technology to be feasible, and the compliance dates in Phase II of the compliance schedule provide time for greater technology and market development to occur, with a technology assessment scheduled for before June 1, 2027. Staff agrees more time is needed for high temperature units, and thus divided Type 2 high temperature units out from the Type 2-unit category. Type 2 high temperature units are subject to Phase III implementation schedule. Staff recognizes that the technology is feasible for heat pumps above 1 MMBtu/hr and that the future implementation dates will allow for greater market growth. The technology assessment scheduled for before June 1, 2027, will consider the market readiness for Type 2 units.

Response to Comment 8-3:

Staff recognizes the need for a compliance tool to differentiate the units allowed to be installed in new and existing buildings. Please see Response to Comment PC-9 or Response to Comment 7-5 for more details.

Response to Comment 8-4:

Staff recognizes that referring to an annual fuel use in therms for low-use is consistent with other boiler and water heater rules and can be a more accurate way to demonstrate low-use than operation hours. Please refer to Response to Comment 7-2 for more detail on low use.

COMMENT LETTER #9

Karen Bass, Mayor
 Board of Commissioners
 Nicole Neeman Brady, Vice President
 Nurit Katz
 Mia Lehrer
 George S. McGraw
 Chante L. Mitchell, Secretary

Martin L. Adams, General Manager and Chief Engineer

March 5, 2024

Mr. Michael Krause, Assistant DEO
 South Coast Air Quality Management District
 21865 Copley Drive
 Diamond Bar, CA 91765

Dear Mr. Krause:

Subject: Los Angeles Department of Water and Power's (LADWP) Comments on Proposed Amended Rule 1146.2 – Emissions of Oxides of Nitrogen from Large Water Heaters and Small Boilers and Process Heaters

LADWP appreciates the opportunity to provide comments on the Proposed Amended Rule (PAR) Rule 1146.2 – Emissions of Oxides of Nitrogen from Large Water Heaters and Small Boilers and Process Heaters. LADWP remains committed to working with the South Coast Air Quality Management District (SCAQMD) during this rulemaking process and looks forward to refining the proposed language in ensuring a successful implementation of the proposed rule.

I. Key Concerns for SCAQMD's Consideration: Recognizing that the proposed transition from gas-powered water heaters, boilers, and process heaters to all-electric alternatives has raised some concerns among the stakeholders, LADWP requests that SCAQMD take into account the following considerations:

9-1

a. Energy Demand and Grid Capacity:

The widespread adoption of electric heating systems across the South Coast Air Basin would result in an increased demand for electricity that could potentially strain local electrical grids. Upgrades to the grid infrastructure may be necessary to accommodate the additional load. Similarly, upgrades to building infrastructure (such as electrical panels and wiring) which would involve detailed design/engineering, permitting, installation, and testing may be necessary to support the increased electrical demand. LADWP appreciates SCAQMD's proposed phased implementation schedule as this could reduce the impact on energy demand but encourages SCAQMD to work with utilities and stakeholders to ensure that the intended electrification of these equipment and the resulting increase in energy demand would not significantly impact grid reliability.

b. Reliability and Resilience:

Interruptions in power supply may disrupt heating systems, impacting the functionality of commercial buildings. In particular, LADWP's water facilities which supply water for the City of Los Angeles are dependent on water heater and boiler operations. Interruptions to power, especially during emergencies, may negatively impact water facility operations. Also, compared their gas-powered counterparts, electric water heaters and boilers have a short track record, making it challenging to assess their long-term reliability and durability.

Mr. Michael Krause
Page 2
March 5, 2024

- | | |
|--|-----------------------|
| <p>c. <u>Technology Maturity and Availability:</u>
There are concerns with the availability of large electric water heaters, small boilers, and process heaters since the market for electric alternatives is currently not as mature and established as their gas counterparts. Though the market is expected to expand in the future, there is no assurance that the electric alternatives available in the market would be reliable and suitable replacements for existing gas-fired water heaters, boilers, and process heaters. Concerns also remain as to whether these electric alternatives would be compatible with current equipment and building specifications. For instance, sizing constraints for existing equipment (e.g. water heaters and boilers that are located in tightly enclosed areas), could pose challenges in finding appropriate replacements.</p> | <p>Cont'd
9-1</p> |
| <p>II. Proposed Updates to the Rule Language: LADWP would also like to propose some updates to the second preliminary draft Rule 1146.2 language for added clarification:</p> | |
| <p>a. Condition (d)(1) states "Prior to the applicable Table 3 compliance dates, no person shall manufacture, supply, sell, offer for sale, or install, for use within the South Coast AQMD, any Unit unless the Unit is certified pursuant to subdivision (f) not to exceed the applicable Table 1 emission limits." However, the intention is to allow water heaters and boilers to operate at the NOx and CO emission limits until the compliance date, or the end of useful life, whichever is later. LADWP's proposed language is as follows:
"Prior to the applicable Table 3 compliance dates <u>or the end of unit useful life, whichever is later</u>, no person shall manufacture, supply, sell, offer for sale, or install, for use within the South Coast AQMD, any Unit unless the Unit is certified pursuant to subdivision (f) not to exceed the applicable Table 1 emission limits."</p> | <p>9-2</p> |
| <p>b. Similarly, for clarity, LADWP proposes a change to Condition (d)(3): "On and after the Table 3 compliance dates, an owner or operator of a Unit shall not operate a Unit which exceeds Table 2 emission limits once the Unit age determined pursuant to subdivision (e) is greater than or equal to the applicable Table 2 Unit age" to the following:
"On and after the Table 3 compliance dates <u>or the end of unit useful life, whichever is later</u>, an owner or operator of a Unit shall not operate a Unit which exceeds Table 2 emission limits <u>once the Unit age determined pursuant to subdivision (e) is greater than or equal to the applicable Table 2 Unit age</u>."</p> | |
| <p>c. LADWP also suggests that SCAQMD include clarification about the Labeling and Reporting Requirements in Condition (j)(1). Since labeling has not previously been required by Rule 1146.2, LADWP requests clarification as to whether these requirements apply to already installed water heater and boilers.</p> | |

Mr. Michael Krause
Page 3
March 5, 2024

LADWP requests SCAQMD's consideration of these comments and other stakeholders' comments and looks forward to working further with SCAQMD during this rulemaking process.

If you have any questions or would like additional information, please contact Ms. Andrea Villarin of my staff at (213) 367-0409 or Ms. Tejasree Ganapa at (213) 367-6332.

Sincerely,

Katherine Rubin Digitally signed by Katherine Rubin

RESPONSE TO COMMENT LETTER #9

Response to Comment 9-1:

Staff appreciates LADWP's comment on PAR 1146.2. The state and local agencies in California are aligned working towards similar policy direction for zero-emission building appliances and are planning for the corresponding future demand for grid capacity, reliability, and resilience. BAAQMD adopted the zero-emission standards effective in 2027 for small water heaters and in 2031 for other space and water heaters in residential and commercial buildings in March 2023. CARB has commenced its rulemaking process for potential state-wide standards to "develop and propose zero-emission standards for space and water heaters sold in California" with potential implementation in 2030 as committed in the 2022 State Strategy for the State Implementation Plan. Many cities and counties have adopted ordinances for zero-emission appliances. The CEC, CPUC, and CARB are working to coordinate across efforts, identify issues not covered by ongoing efforts, and assess needed actions such as infrastructure upgrades to better align the energy system with the state's climate targets and electrical demand. The CEC adopts an IEPR every two years and an update every other year, and the ~~2022~~2023 IEPR has recognized the proposed zero-emission requirements for residential and commercial buildings in California and included recommendations and updates to the energy demand forecast. Furthermore, CAISO is planning billions in transmission capacity projects over the next 20 years, and the 20-Year Transmission Outlook document from May 2022 considers transmission needs to meet load and renewable energy growth aligned with state policy. In 2021, the CPUC created new programs and modified existing programs to reduce energy demand and increase energy supply during critical hours of the day. Per Senate Bill 350 (De León, 2015), the CPUC developed an integrated resource planning process to ensure that California's electric sector meets its greenhouse gas reduction goals while maintaining reliability at the lowest possible costs. On the utility level, according to SCE's 2021 Sustainability Report, SCE is expected to invest significantly in the electric grid, including energy storage. SCE also expected increases in Distributed Energy Resources such as solar. In 2021, according to the CEC, renewable generation accounted for 33.6 percent of the total California Power Mix, not including solar photovoltaic systems installed on residential and commercial buildings that are less than one MW as they are typically considered distributed generation and not required to report to CEC. There is expected to be more renewables adoption by states in the future, and California Senate Bill 100 called for a Renewables Portfolio Standard of 60 percent by 2030. Electricity imports account for approximately 30 percent of total system electric generation, with other states pursuing Renewable Portfolio Standards and state energy goals.

Staff has accounted for potential infrastructure upgrades in the cost-effectiveness analysis and included alternative compliance options related to potential utility upgrades and emergency replacement situations. The future effective dates will allow for reduced impact on energy demand, and many existing units will be replaced when they reach their unit age which may be after the compliance dates which will result in a slower, phased transition to zero-emission technologies.

Zero-emission technologies such as heat pump water heaters and electric resistance water heaters and boilers have been in operation for years and continue to be installed in various

applications. Staff expects the capital costs for heat pumps to decrease over time in the lead up to future effective dates and beyond as the market matures and availability increases.

Regarding spacing, please refer to Response to Comment PW-2 for more details.

Response to Comment 9-2:

Staff appreciates the suggestion for rule language. Prior to the Table 3 compliance dates, whether the unit is at the end of unit age or not, Table 2 emission limits apply. Units reaching their unit age after the zero-emission compliance dates of their applicable categories are required to phase into the zero-emission requirement. Staff believes the mentioned rule language clearly expresses the intent without revising the rule language.

Regarding the labeling and reporting requirement, the labeling requirements do not apply to already installed water heaters and boilers.

COMMENT LETTER #10

**COMPACT, HIGHLY EFFICIENT, QUICK STARTING
STEAM GENERATOR SYSTEMS**

March 8th, 2024

Subject: SCAQMD Rule 1146.2 potential rule change

Attention: Michael Krause -Assistant DEO, 909-396-2706, Emily Yen – Assistant Air Quality Specialist, 909-396-3206, Heather Farr – Planning & Rules Mgr., 909-396-3672

To whom this may concern:

Clayton Industries opposes the proposed rule change which in effect would require all small steam boilers to be electric only. Opposition is based on the following:

It would present an economic hardship to our customers:

- a) These customers have already paid a premium for SCAQMD pre-certified equipment.
- b) Infrastructure does not exist to bring newly required electrical power into most facilities effected. Targeted small commercial boilers typically used by small businesses/manufacturers that would now be forced to make very expensive upgrades that may not even be possible in some cases due to permitting/zoning, economic requirements. (example: 49 BHP boiler, even if they had three phase/ high voltage power available, would need 600 amps to run at 460volts. The amperage would be even higher if they used lower voltage or single- phase power!)
- c) Cost of running an electrical boiler is substantially more expensive than running on gas due to high cost of electricity.
- d) Increased dependence on a less reliable power source will make it more difficult to run a business. Without electrical power, the boiler and work/services will be off- line.

It will further perpetuate California's hostile business environment to the detriment of Californians:

- a) Many small manufacturers and services (dry cleaners for example) may be forced to relocate or go out of business.
- b) This will discourage many new companies from manufacturing/processing or providing services in California.
- c) With less good paying jobs, the middle class will continue to be pushed out of California.
- d) The above means less tax revenue that adds to California's financial problems.

Clayton Industries
17477 Hurley Street, City of Industry, CA 91744
www.claytonindustries.com

COMPACT, HIGHLY EFFICIENT, QUICK STARTING
STEAM GENERATOR SYSTEMS

It is not practical at this time:

- a) Aside from the electrical current capacity limitation of local users, the power grid throughout California is already having trouble keeping up with current statewide electrical requirements, evidenced by rolling blackouts and the high cost of electricity.
- b) even the push for electric car mandates has had to deal with the realities of the current electric grid.
- c) The latest low NOx gas fired burners provide extremely low levels of air pollution.
- d) Majority of air pollution caused by vehicle emissions.
- e) The impact to small businesses would be too large in relation to the actual impact to the overall air pollution problem.

10-3

Recommendation:

Rather than go to the extreme of all electric boilers, reduce the NOx limit from 20ppm to 15ppm, CO under 50ppm, and requirement for full premix burners.

10-4

We hope that the SCAQMD will re-consider this radical change.

Sincerely,

Brian T. Dominici

RESPONSE TO COMMENT LETTER #10**Response to Comment 10-1:**

Staff appreciates Clayton Industries' comment on PAR 1146.2. The proposed zero-emission limits will not take effect until future compliance dates for new installations, and at the end of the presumed unit age of the equipment currently being used; therefore, the majority of the cost impacts are at the natural turnover of the equipment. The facilities will incur some cost to upgrade the equipment, but some of the cost will already be incurred due to end-of-unit-age replacement. The boiler example described by the commenter appears to be a large unit for industrial use with a heat input capacity beyond PAR 1146.2's applicability. Units with a rated heat input capacity greater than 2 MMBtu/hour are subject to either Rule 1146 or 1146.1, depending on the rated heat input capacity, which have lower emissions limits than Rule 1146.2 but are not transitioning to zero-emission limits at this time. In addition, staff included alternative compliance options to address utility upgrade and emergency replacement concerns and later implementation dates to give more time for units in existing buildings to be replaced and for high temperature unit installations. Boilers for output water temperature higher than 180 degrees Fahrenheit will not be subject to zero-emission limit until 2033. Staff also committed to a technology assessment by June 1, 2027, to review technology development and market availability and address any further concerns.

Common zero-emission water heating technology includes heat pumps, which can be over three times more efficient than conventional appliances. The CEC adopts an Integrated Energy Policy Report (IEPR) every two years and an update every other year. The IEPR update released on January 1, 2024, provided forecasts for future natural gas and electricity rates, which staff utilized in the cost-effectiveness analysis. As the newest IEPR projected the natural gas rate to increase 40% and electricity rate to have a more moderate increase of 28%, this resulted in increased cost savings from fuel switching in the cost-effectiveness analysis for transitioning to heat pumps. Most categories for heat pump replacements were below the cost-effectiveness screening threshold, ranging from cost-effectiveness savings of \$190,000 to cost-effectiveness of \$264,000 per ton of NOx reduced. The Type 1 high temperature category was above the screening threshold at around \$580,000 per ton of NOx reduced, and staff is proposing a longer compliance schedule for high temperature units to comply with zero-emission limits. Costs are expected to decrease as technology matures, and a future technology check-in will provide further cost analysis prior to compliance dates for high temperature units.

Staff recognizes the importance of electric grid reliability for electric units, but also for natural gas units, which often require electricity to operate. The CEC, CPUC, and CARB are working to coordinate across efforts, identify issues not covered by ongoing efforts, and assess needed actions to better align the energy system with the state's climate targets. Please see Response to Comments 4-1 and 9-1 for more on electric grid reliability.

Response to Comment 10-2:

Staff recognizes the concerns of small businesses and added an exemption for small businesses from the unit age requirement, so that small businesses can operate their equipment beyond the rule defined unit age. Staff gathered cost data for various types of units for the cost-effectiveness analysis described in Chapter 2 of this report. Heat pumps are the primary zero-emission technology. The analysis accounted for higher equipment and installation cost, operational cost of switching from gas to electricity, and electrical upgrade cost for some cases. Although the analysis determined that it is cost-effective for most of the equipment categories to implement zero-emission [standards](#), staff understands the challenge of higher upfront costs. Staff is in the process of developing a rebate program to help lower the cost for some consumers and centralizing information for incentive and financing opportunities offered by other agencies and organizations. Please refer to Response to Comment 6-1 for more detail. Further, as zero-emission technologies become more mature and more widely adopted in the market in the future, there will be less cost impact.

To address further concerns, PAR 1146.2 provides alternative compliance options to address specific concerns including emergency replacement, utility upgrades, replacement of five or more units with the same compliance year, and other cases. PAR 1146.2 is accompanied by a socioeconomic impact assessment which considers potential impacts to job growth forecast, among other metrics.

We should also recognize the health benefit to the communities. BAAQMD evaluated ambient air quality and health impacts from natural gas-fired furnaces and water heaters in commercial and residential buildings in support of the zero-emission standards BAAQMD adopted in March 2023. According to the BAAQMD staff report, the proposed zero emission space and water heaters in residential and commercial buildings will result in reductions in NOx emissions and reductions in secondary PM2.5 across the Bay Area.⁷³ These reductions in secondary PM2.5 avoid an estimated 23 to 52 deaths per year and about 71 new cases of asthma per year. Reductions in total PM2.5 attributable to the targeted appliances, including reductions in primary PM2.5 from adoption of electric appliances, would avoid an estimated 37 to 85 premature deaths per year and about 110 new cases of asthma each year. The valuations of the health impacts from total PM2.5 were estimated to be between 400 to 890 million U.S. dollars annually. Similar benefits would accrue to communities in the South Coast AQMD.

Response to Comment 10-3:

Regarding electric grid supply and reliability, please refer to Response to Comment 4-1.

As the South Coast Air Basin has been classified as “extreme” nonattainment for the 2015 ozone standard, staff is required to consider emission reduction for all categories and set future effective dates to reduce emissions as early as feasible. The estimated baseline emissions for PAR 1146.2 is around nine percent of the total stationary source inventory. Staff also considers that South Coast AQMD standards cannot be less stringent than state-wide standards. CARB has commenced its rulemaking process for potential state-wide standards to “develop and propose zero-emission standards for space and water heaters

sold in California” with potential implementation in 2030 as committed in the 2022 State Strategy for the State Implementation Plan.

Staff gathered cost data for various types of units for the cost-effectiveness analysis described in Chapter 2 of this report, which was discussed with the Working Group throughout the rule development process. The analysis accounted for higher equipment and installation costs, operational cost of switching from gas to electricity, and electrical upgrade costs. Although the analysis determined that it is cost-effective for most of the equipment categories to implement zero-emission, staff understands the challenge of higher upfront cost. During the rule development process, staff strives to maximize emission reductions while considering cost-effectiveness. The cost-effectiveness threshold is neither considered a starting point or absolute cap for control costs, nor an enforcement tool. Instead, it provides a guide during rule development to identify cost-effective control options. Staff is committed to identifying and proposing cost-effective control options, while striving to achieve the emission reductions necessary for regional air quality attainment, especially given the magnitude of the emission reductions needed to meet the ozone standards.

Response to Comment 10-4:

PAR 1146.2 only applies to a subset of large water heaters and small boilers and process heaters. At this time, South Coast AQMD is not proposing all boilers transition to zero-emission limits – only the units less than 2 MMBtu/hour. Staff conducted a thorough technology assessment for PAR 1146.2 to evaluate the NO_x control technologies that will achieve the BARCT level equipment subject to PAR 1146.2. The final proposed zero-emission limit for each class and category is the emission limit that achieves the maximum degree of emission reductions and is determined to be cost-effective and feasible with future year implementation. With regards to the commenter calling zero-emission standards for building appliances “extreme,” other agencies are considering or have already adopted similar rules, and a South Coast AQMD rule cannot be less stringent than a state-wide rule. CARB has commenced its rulemaking process for potential state-wide standards to “develop and propose zero-emission standards for space and water heaters sold in California” with potential implementation in 2030 as committed in the 2022 State Strategy for the State Implementation Plan. The CEC 2022 Building Energy Efficiency Standards (Energy Code) apply to newly constructed buildings and additions and alterations to existing buildings. The 2022 Energy Code encourages efficient electric heat pumps, establishes electric-ready requirements for new homes, expands solar photovoltaic and battery storage standards, and more. BAAQMD adopted Rule 9-6 – Nitrogen Oxides Emissions from Natural Gas-Fired Boilers and Water Heaters in March 2023 with zero-emission limits for 2031 implementation. Some manufacturers are opposed to interim lower NO_x emission limits when zero-emission limits are deemed feasible for future implementation and will be the ultimate policy direction. Those manufacturers would be focused on expanding zero-emission products, instead of spending resources on developing lower NO_x emission technologies for an interim time period.

COMMENT LETTER #11

The Boeing Company
4000 Lakewood Blvd.
Long Beach CA 90808-1700

March 04, 2024

SCAQMD
21865 E. Copley Drive
Diamond Bar, CA 91765

ATTN: Heather Farr
Planning and Rules Manager

Re: SCAQMD Rule 1146.2 Proposed Amendments

Thank you for the opportunity to provide comments relating to the proposed amendments to SCAQMD Rule 1146.2 (Emissions of Oxides of Nitrogen From Large Water Heaters and Small Boilers and Process Heaters). Boeing requests that the following changes be incorporated into the proposed amendments to the rule:

- Proposed Amended Rule 1146.2 (Table 2) assigns a life expectancy (unit age) of 15 Years for Type 1 units and 25 years for Type 2 units. The Boeing Company (Boeing) typically sees longer life expectancy for these types of units due to the maintenance programs employed by the company. Even the draft staff reports states that 25 years is used for Type 1 and Type 2 boilers (Page 2-15) with respect to the cost-effectiveness analyses. Boeing requests that the unit age for Type 1 boilers be increased to 25 years and Type 2 boilers increased to 30 years. 11-1
- PAR 1146.2 (d)(9) provides that Type 1 and Type 2 units that do not meet specified NOx limits must be removed from service within one year after rule adoption. Boeing anticipates having to replace a number of units currently in the RECLAIM program and the specified time frame is insufficient to allow replacement. Boeing has replaced several of these units over the past few years. The projects typically takes anywhere from 12-18 months for planning, permitting and installation, assuming there are no issues with delivery of equipment. In addition, this relatively short time frame does not allow adequate time to perform the necessary engineering evaluations to determine if a switch to heat pumps might be a suitable approach. Boeing requests that the compliance dates contained in Table 3 for existing equipment be utilized for these units. 11-2
- PAR 1146.2 (g)(1) requires that copies of source tests be retained onsite. These reports are usually maintained at a central office and Boeing requests that the language in recently adopted SCAQMD Rule 1147 (h)(8) be utilized in lieu of the proposed language. 11-3
- PAR 1146.2 (h)(3) specifies that the owner/operator maintain documentation identifying the rated Heat input capacity of the unit. The manufacturer's label on the unit specifying the required information should be sufficient to meet this requirement. 11-4
- PAR 1146.2 (i)(1) specifies requirements for obtaining relief with respect to the lack of power availability at a facility. Utility upgrades, especially for larger facilities, may be a multi-year project. Is the intent that a company will have to request a new extension every year from SCAQMD until the facility has completed the work, since the company will have spelled out the 11-5

The Boeing Company
4000 Lakewood Blvd.
Long Beach CA 90808-1700

specific requirements in (i)(1)(D)? With respect to (i)(1)(C), notification period should be changed to 72 hours to allow adequate time for internal review, especially if completion occurs over weekends or holidays. Boeing also seeks clarification on what information is required under (i)(1)(D)(i)(E). Companies are dependent upon the utility to provide the necessary infrastructure upgrades and the associated time table for when the upgrades will be completed. Boeing is unsure what information SCAQMD is requesting in this section that demonstrate delays are beyond the control of the owner/operator.

Boeing looks forward to continuing to work with District staff in the development of the proposed amendments to SCAQMD Rule 1146.2. Note that we are continuing to assemble cost and emission information for the Boeing facilities and are working to providing the additional information this week. If you should have any questions or require additional information, please do not hesitate to contact me.

A handwritten signature in black ink, appearing to read 'W Pearce', with a long horizontal line extending to the right.

William Pearce
Senior Environmental Engineer
Environmental Services
Environment, Health & Safety

RESPONSE TO COMMENT LETTER #11**Response to Comment 11-1:**

Staff appreciates Boeing's comment on PAR 1146.2. Please refer to Response to Comment 1-3 for discussion on unit age.

Response to Comment 11-2:

Staff agrees that RECLAIM and former RECLAIM need more time to replace the existing units that are not meeting the NOx standards of 30 ppmv for Type 2 units and 55 ppmv for Type 1 units. Staff removed the lower NOx requirements previously proposed in paragraph (d)(9). This proposal revision means RECLAIM and former RECLAIM facilities will be subject to paragraph (d)(3) of PAR 1146.2 for zero-emission requirements once the existing units reach their unit age on and after the applicable Table 3 compliance dates. This change allows facilities to keep operating older units and will potentially achieve higher emission reductions as facilities will not be required to replace older units with newer combustion units that can operate for an additional 25 years; facilities will have the option to continue to operate the older units until the future effective zero-emission limits go into effect.

Response to Comment 11-3:

Staff agrees with the comment and revised the proposed amended rule. The owner or operator will be required to make the copies of source tests available to the Executive Officer upon request, instead of retaining the copies onsite.

Response to Comment 11-4:

The provision regarding rated heat input capacity documentation is PAR 1146.2 paragraph (j)(5) is an existing requirement. This provision streamlined recordkeeping requirements in existing Rule 1146.2 paragraph (c)(10) for rated heat input capacity documentation. The definition for rated heat input capacity in both the existing rule and proposed amended rule specifies that the gross heat input shall be supported by required documentation, and which shall be specified on a permanent rating plate. Requiring documentation is especially important when the burner of a unit is modified. The documentation must be signed by the licensed person modifying the unit and the rating plate must be updated accordingly as required by the rule. Staff does not agree with the suggestion to change the proposal to only require the rating plate or label on the unit for the demonstration of rated heat input capacity.

Response to Comment 11-5:

Staff revised paragraph (i)(1). The owner or operator of the unit is provided ~~18~~²⁴ months additional time to comply if a utility upgrade is required and the applicable utility company is unable to provide the necessary power to operate the unit, which is causing a delay beyond the facility's reasonable control. In addition, the owner or operator can request an extension of an additional ~~18~~²⁴ months and an additional 12 months. The total allowed delay in this situation is up to ~~36~~⁶⁰ months. When there are also multiple units subject to the situation, the owner or operator can submit an alternative compliance plan for the

scheduled extended implementation as specified in paragraph (i)(2). The owner or operator may seek variance or other alternatives beyond PAR 1146.2 if further relief is needed.

Regarding the comment on notification period, staff agrees and changed the notification period from 24 hours to 72 hours to provide adequate time for internal review. Regarding documentation which demonstrates that the delays are beyond the reasonable control of the owner or operator, this could be documentation showing timely communication, utility companies' statements, contract for the work with projected work plan, etc. A good example would be a letter from the utility that says the issue is on the utility side of the meter.

COMMENT LETTER #12**California Council for Environmental and Economic Balance**

369 Pine Street, Suite 720, San Francisco, CA 94104

(415) 512-7890 | cceeb.org

March 13, 2024

Mr. Michael Krause, Assistant DEO
South Coast Air Quality Management District
21865 Copley Drive
Diamond Bar, CA 91765

Dear Mr. Krause:

Subject: Comments on Proposed Amended Rule 1146.2 – Emissions of Oxides from
Large Water Heaters and Small Boilers and Process Heaters

The California Council for Environmental and Economic Balance (CCEEB) is a coalition of business, labor and public policy leaders that work together in pursuit of balanced and effective policy solutions. Many CCEEB member organizations operate large facilities in the South Coast Air Quality Management District (SCAQMD or “District”) and, as such, we are closely following the development of PAR 1146.2.

While CCEEB recognizes the need to transition to zero emission (ZE) and low-NOx technologies where feasible, we also recognize these strategies are far more complex and costly to implement than other strategies developed by the District. Additionally, CCEEB recognizes that some of these concerns have been previously communicated to the District, and in reiterating these concerns, CCEEB intends to highlight the importance and potential impacts of these rulemaking decisions. CCEEB wishes to focus its comments on three areas of the proposal:

1. Concern with the Availability of Sufficient Energy to Implement this Proposal

While CCEEB supported the adoption of the 2022 AQMP, we raised the concern to staff and the Board that initiatives to electrify large sectors could strain the grid. The 1146.2 rule, as proposed, is a prime example of the concern we raised in our comments to the SCAQMD where we stated:

“Mandates to deploy ZE technologies must be closely aligned and coordinated with development of energy infrastructure and maintaining system reliability. This is particularly important for the state’s electrical grid, which must respond to several

12-1

2

equally important but overlapping mandates, such as the shift to 100% renewable and carbon-free electricity generating resources and a “hardening” of the system to prevent and protect against catastrophic wildfires.”

CCEEB encourages the District to work with state agencies, the utilities and all stakeholders to ensure that the proposal takes into consideration, and adjusts where necessary, its potential impact on the grid. Facilities that need to upgrade power have to take into account demands from switching all types of equipment to electric at relatively the same time. Thus, some publicly-owned utility providers may have even greater difficulty providing facilities with enough electricity in time to meet the demands of 1146.2 and other proposed zero-emission rules.

2. Cost-Effectiveness Does Not Take Into Account the Degree of Work Necessary to Make these Transitions

12-2

SoCalGas, a CCEEB member, articulated this point to the District quite well in its March 8 comment letter.

“The South Coast AQMD’s cost-effectiveness analysis has focused on single pieces of equipment at a single facility. It has not evaluated the cost associated with retrofits at larger commercial and/or industrial facilities that have multiple affected pieces of equipment, many of which are located in multiple buildings/structures on the site. The South Coast AQMD has also not included cost for cutting concrete and/or asphalt and trenching to distribute new on-site electrical power distribution to these pieces of equipment and/or buildings, which will be the costliest aspect of conversion.”

This concern has been echoed by many CCEEB members. Again, in our comments to the 2022 AQMP, CCEEB stated:

“Given the range of costs associated with ZE technology and the significant degree of uncertainty, the District will need to work closely with stakeholders and other partners in developing a reliable way to assess a fair scope of costs. An added challenge is the robustness of low-NOx controls, which lowers the marginal benefit of ZE strategies. How the District will apply its cost-effectiveness thresholds will be important. Similarly, staff assessments of technological feasibility will be more complicated than ever before. In its work, the District can serve as an important model for other jurisdictions.”

3. Implementation Periods Need to be Extended

12-3

Many CCEEB members are in the RECLAIM program and, as such, CCEEB has a particular concern with PAR 1146.2 (d)(9). As we understand the proposal, the current language requires Type 1 and Type 2 boilers that do not meet specific NOx limits to be removed from service within one year of rule adoption. Many of our organizations have multiple units that would fall into this category and CCEEB does not believe it is feasible to make this

3

changeover in such a tight window. Further, the proposal is not clear as to why RECLAIM facilities are called out with this short compliance deadline. CCEEB requests compliance dates contained in Table 3 for existing equipment to be utilized for these units.

For facilities with multiple units, we appreciate staff's addition of the Alternate Compliance Option. Even with this option, the time to plan, obtain additional power, and install for these larger facilities will likely result in some facilities being unable to achieve compliance within the 3-year phased option as described in section (i)(2)(B). CCEEB requests the District to consider a 5-year phased-in approach (20% of units per year) for facilities with more than 20 units.

12-4

Given the significance of our comments above and the fact that several of our members are working closely to provide more accurate information on cost-effectiveness, we sincerely request a one-month delay in moving this proposal forward to the Board for an April Set Hearing and a May Public Hearing.

CCEEB recognizes the importance of this proposal and, along with our members, commits to work with you to find solutions to these concerns. Thank you for considering our comments.

Sincerely,

William J. Quinn
CCEEB Consultant

cc: Tim Carmichael, CCEEB President
Allegra Curiel, CCEEB
Members, CCEEB's South Coast Air Project

RESPONSE TO COMMENT LETTER #12

Response to Comment 12-1:

Staff appreciates CCEEB's comment on PAR 1146.2. Please see Response to Comment 9-1.

Response to Comment 12-2:

The cost-effectiveness analysis for BARCT is to evaluate the incremental cost per ton of emission reductions by retrofitting or replacing a type of equipment with newer technologies. This analysis is equipment based, and it considers incremental installation and electrical upgrade costs as explained in Chapter 2 of this staff report. Although the cost-effectiveness does not evaluate the total cost for a facility with multiple units, the socioeconomic impact analysis for this project, ~~a draft of~~ which ~~will be~~was released ~~30 days~~ prior to the public hearing for PAR 1146.2, assesses the total cost impact for the region. [The Final Socioeconomic Impact Assessment is available in Attachment H of the June 7, 2024, Governing Board Package.](#)

Regarding the installation cost, staff recognizes that there may be some cases where a utility upgrade is required and could include trenching, which can add additional cost. While trenching is costly, the end user would not bear the full cost when the trenching is required before the facility's meter. Furthermore, not every unit replacement will require trenching. Staff acknowledges that alternative compliance options could be useful in cases where a utility upgrade is needed, or multiple units need to be replaced. Regarding alternative compliance options for utility upgrades and multiple units, please see Response to Comment 5-3. Please refer to Response to Comment 7-1 for further details on the cost-effectiveness threshold.

Response to Comment 12-3:

Please see Response to Comment 11-2 regarding RECLAIM units. Please see Response to Comment 11-5 regarding multiple units.

Response to Comment 12-4:

Staff has been available throughout the public process to meet with stakeholders and appreciates any further input or data that may be provided.

Re: Second Preliminary Draft Rule: Proposed Amended Rule 1146.2(d)(7)

Dear Ms. Zhu:

The Regents of the University of California (“University”), on behalf of its campuses in Los Angeles, Irvine, and Riverside, has discovered what it believes to be an error in the Second Preliminary Draft of Proposed Amended Rule 1146.2, and would like to bring this error to the Air District’s attention before the Draft Rule is officially released for public review on April 2, 2024.

Specifically, the University believes an error exists in PAR 1146.2(d)(7). Subsection (d)(7) proposes: “An owner or operator shall not operate any Type 1 Unit manufactured prior to January 1, 2012, in the South Coast AQMD which does not meet the NOx emission limit of 55 ppmv.” As written, this amendment would immediately prohibit the use of Type 1 Units manufactured and in operation prior to January 1, 2001, with emissions exceeding 55 ppm NOx. We do not believe this reflects the Air District’s intent for two reasons:

1. *Existing* Rule 1146.2 does not expressly prohibit the use of Type 1 Units manufactured and in operation before January 1, 2001, even if emissions exceed 55 ppm NOx.
2. Tables 2 and 3 in PAR 1146.2 include a phase-out schedule for Type 1 Units manufactured and in operation before January 1, 2001.

If subsection (d)(7) is adopted as proposed, the compliance schedule in Tables 2 and 3 would be rendered meaningless because Type 1 Units manufactured before January 1, 2001 that exceed 55 ppm would need to immediately cease operation upon the Rule’s effective date. In other words, our campuses and any other facilities with pre-2001 Type 1 Units would be forced to leave buildings unheated without any opportunity to phase out these Units in accordance with proposed Tables 2 and 3.

For the above reasons, the University requests that PAR 1146.2(d)(7) be modified to correct this error. The University proposes the following edit for the Air District’s consideration: “An owner or

13-1

South Coast Air Quality Management District
March 15, 2024
Page 2

operator shall not operate any Type 1 Unit manufactured after January 1, 2001, and prior to January 1, 2012, in the South Coast AQMD which does not meet the NOx emission limit of 55 ppmv.”

The University recognizes that the Air District has yet to open a formal comment period on the Draft Rule, but we believe this error is significant enough that subsection (d)(7) should be changed before the formal comment period begins.

Thank you for your consideration of this concern and related request.

Sincerely,

Ken Smith, CHP CIH RRPT
Executive Director of Environment Health & Safety

cc: Sarah Quiter, UC Legal Principal Counsel

13-1

RESPONSE TO COMMENT LETTER #13**Response to Comment 13-1:**

Staff appreciates the University of California's comment on PAR 1146.2.

Staff understands Preliminary Draft PAR 1146.2 paragraph (d)(7) for Type 1 units is not in existing Rule 1146.2; however, previous rule language was for 15 years of unit age (useful life) and current PAR 1146.2 language includes 15 years of unit age for Type 1 units that are not high temperature units or instantaneous water heaters. Thus, staff expected Type 1 units would have been phased out by now through natural turnover and did not anticipate the provision would result in stranded assets. That said, staff agrees that it is more meaningful to replace those old Type 1 units with zero-emission units on and after Table 3 compliance dates and that approach is estimated to result in more lifetime emission reductions. Therefore, staff is proposing to remove paragraph (d)(7). Type 1 units manufactured prior to January 1, 2001, with emissions exceeding 55 ppmv NO_x limit will be required to transition to zero-emission technologies based on the future effective dates in Table 3.

COMMENT LETTER #14

March 27, 2024

Emily Yen
 Planning, Rule Development, and Implementation
 South Coast Air Quality Management District
 21865 Copley Drive
 Diamond Bar, CA 91765

Re: Rule 1146.2 Second Preliminary Draft of Rule 1146.2

Dear Ms. Yen:

On behalf of Bradford White Corporation (BWC), we would like to thank you for the opportunity to comment on South Coast Air Quality Management District's (SCAQMD) Second Preliminary Draft of Rule 1146.2, dated February 20, 2024.

We have compiled our comments and questions to the Second Preliminary Draft of Rule 1146.2 below.

General

BWC has reviewed the Second Preliminary Draft of Rule 1146.2, and we appreciate staff's consideration of our comments and other stakeholders, as reflected in the current draft. In particular, alignment of the new construction compliance dates for Type 1 Water Heaters and Instantaneous Water Heaters rated 200,000 Btu/hr and under with the California Energy Code cycle, the inclusion of an exception process for utility delays and extending compliance dates for mobile homeowners. However, BWC has concerns regarding the reintroduction of labeling requirements, along with the newly introduced annual reporting requirements for equipment.

14-1

Product Labeling

The Second Preliminary Draft of Rule 1146.2 proposes to require manufacturers to affix labels to equipment identifying the Unit as "For installation and use in existing buildings only." In addition, the draft proposes a second labeling requirement for instantaneous water heaters that would take effect in 2029 labeling these products as "For Installation and Use in Mobile Homes Only." As stated in our previous letter dated January 19, 2024, and repeated below, we strongly believe the proposed labeling requirement, as written, is unnecessary to enforce the rule and will add significant burdens to compliance for manufacturers of regulated products:

14-2

Built to be the Best™

725 Talamore Drive • Ambler, PA 19002-1873 • 215-641-9400 • www.bradfordwhitecorporation.com

“SCAQMD currently maintains a qualified products list¹ for all manufacturer water heating and boiler models certified under Rule 1146.2. To enforce the proposed Zero NOx implementation dates, SCAQMD could simply modify their table to show models that are allowed in new construction and models that are only allowed in existing buildings. Secondly, new construction requires plans to be submitted to building jurisdictions to review, as well as Title 24 energy modeling. SCAQMD can work with building jurisdictions within their territory that review and approve project plans to enforce the use of Zero NOx water heating and boiler equipment. Lastly, new construction projects are permitted and require building inspectors to approve the construction. If a non-compliant product were to be installed, it could ultimately be flagged for removal by the building inspector.”²

We understand that the intent of the labels is to aid the District’s inspectors in verifying equipment in the field. However, as currently proposed, the labeling nomenclature will create market confusion outside of the SCAQMD territory. If the District maintains that a labeling requirement is necessary instead of utilizing its qualified products list, we strongly encourage the District to provide manufacturers and our wholesalers autonomy as to how we label our products. We request the District remove the specific language requirement and replace it with a more generic statement, such as “affected products must include a mechanism to verify local emissions limits.” We would like to discuss this alternative in more detail with the District prior to implementation of the rule.

14-3

Product Reporting

BWC does not agree with the newly proposed annual reporting requirements for manufacturers. As a manufacturer, we have limited influence or knowledge on where a product will ultimately be installed after it is manufactured. Manufacturers have limited capability to control a product’s final installation location. We are unclear as to why the District believes annual reporting of product sales will be necessary.

The phased, compliance schedule, as outlined in the proposed rule, clearly shows which product categories cannot be sold within the District after a specified date. We would like to request further discussion with the District regarding the reporting requirements and the purpose they will serve to enforce the proposed rule. Furthermore, if reporting is to be required, we ask that the District use the manufacture date of equipment, consistent how other regulatory bodies implement requirements, including the Bay Area Air Quality Management District³, and not the date of sale or installation.

In closing, we encourage SCAQMD to reconsider the labeling requirements altogether. However, if the District maintains labeling requirements, we strongly encourage revising the language, revising the reporting requirements to reduce compliance burdens on product manufacturers and adopt the manufacture date as the date of compliance. We welcome continued dialogue on these matters and would be pleased to have further, direct, conversations with District staff.

Please let me know if you have any questions or would like to schedule a meeting to discuss our comments further.

Respectfully Submitted,

RESPONSE TO COMMENT LETTER #14**Response to Comment 14-1:**

Staff appreciates Bradford White Corporation's comment on PAR 1146.2 and participation in the rulemaking process.

Response to Comment 14-2:

The labeling requirement by paragraph (j)(2) for mobile homes is similar to the labeling requirement by paragraph (j)(1) for existing buildings, where the unit can be installed in some buildings but not others. Instantaneous water heaters with the labeling requirement for the specified period are only allowed for installations in mobile homes, not in other buildings. The labeling requirement is important to educate and remind the buyer of an unpermitted unit. Please refer to Response to Comment PC-9 for a further discussion on labeling.

Response to Comment 14-3:

The reporting requirement is intended to better understand how many natural gas units would be installed following the provisions of the exemption and alternative compliance sections. Since those are unpermitted units without sufficient installation records, the reporting requirement will provide emission inventory data that can be utilized for future evaluation of the benefit achieved by the rule. Manufacturers have reported units distributed to the region through previous Rule 1121 and Rule 1111 mitigation fee compliance options. The reporting for PAR 1146.2 could be similar, except there would be no associated fee.

Subject: Comments on the Initial Preliminary Draft of Proposed Amended Rule 1146.2

Dear Ms. Zhu:

Southern California Gas Company (SoCalGas) appreciates the opportunity to provide public comments on the South Coast Air Quality Management District (South Coast AQMD) Initial Preliminary Draft of Proposed Amended Rule (PAR) 1146.2. SoCalGas has multiple facilities which will be affected by this rule and has been an active participant in the South Coast AQMD rulemaking. SoCalGas recommends South Coast AQMD provide an adequate compliance schedule for entities with multiple facilities in order to accommodate the heavy workload necessary to design, engineer, contract, equipment/materials procurement and construction of these new equipment.

15-1

SoCalGas supports policies incentivizing the adoption of zero-emissions appliances and equipment as part of a broader strategy to achieve NO_x reductions, provided such policies are feasible, permitted by federal law, cost-effective, and commercially available. However, SoCalGas has concerns that the proposed rule effectively bans certain appliances covered by the federal Energy Policy and Conservation Act (EPCA).

15-2

Under a recent ruling by the Ninth Circuit, *California Restaurant Association v. City of Berkeley*, 89 F.4th 1094 (9th Cir. 2024) the Court held that EPCA preempts all regulations “that relate to ‘the quantity of [natural gas] directly consumed by’ certain consumer appliances at the place where those products are used.” *Id.* at 1101. “[A] regulation on ‘energy use’ fairly encompasses an ordinance that effectively eliminates the ‘use’ of an energy source.” *Id.* at 1102. Here, similar to the Berkeley ordinance, the effect of the proposed rule is to reduce the quantity of gas consumed by EPCA-covered appliances to zero. Under *Berkeley*, States and localities cannot avoid EPCA’s

preemption provisions “by doing *indirectly* what Congress says they can’t do *directly*.” *Id.* at 1107 (emphasis in original).

Putting EPCA aside, the South Coast AQMD’s cost-effectiveness analysis has focused on single pieces of equipment at a single facility. It has not evaluated the costs associated with retrofits at larger commercial and/or industrial facilities that have multiple affected pieces of equipment, many of which are located in multiple buildings/structures on the site. The South Coast AQMD has also not included costs for cutting concrete and/or asphalt and trenching to distribute new on-site electrical power distribution to these pieces of equipment and/or buildings, which will be the costliest aspects of conversion.

The South Coast AQMD should perform an analysis that incorporates this type of cost and its impact on cost-effectiveness. This type of cost, as well as other costs, have not typically been accounted for in the South Coast AQMD’s previous Best Available Retrofit Control Technology (BARCT) rule analyses, as historically, BARCT rules only required retrofits (burners or add-on emission controls) or replacement of existing natural gas fueled equipment with similar natural gas fueled equipment which had a much smaller reconstruction cost and footprint. Replacement with electric driven equipment is a much different project with new construction beyond the equipment location and new power supply requirements. These new costs must be included when evaluating a project’s cost-effectiveness. Due to these and other factors, the cost-effectiveness of transitioning existing buildings to zero emissions space and water heating equipment can vary significantly.

Accordingly, based on the information provided at the PAR 1146.2 workgroup meetings and SoCalGas’ meeting with South Coast AQMD staff in January, we asked Ramboll to apply the South Coast AQMDs cost-effectiveness analysis technique of the proposed zero emission standard for Large Water Heaters, Small Boilers and Process Heaters (Appendix) to get a better understanding of the actual installation costs associated with the transition to electric water heaters and boilers at our facilities. SoCalGas recently presented this information to South Coast AQMD staff and will follow up with additional information requested in that meeting. The analysis shows that:

- With design and engineering costs and electrical infrastructure upgrade costs (including the concrete cutting and trenching mentioned above) included in the cost effectiveness (CE) calculations for new zero-emission units, replacing 5 NG units with electric resistance heaters and boilers incurred an incremental installation cost of approximately \$1.81 million, while heat pumps resulted in even higher costs at \$1.89 million. This is significantly higher than the incremental installation cost assumptions in Staff’s CE calculations.
- Zero-emission units are not cost effective when all components of the installation costs are considered in the CE analysis. The CE values are between \$2.6 million and \$5.4 million dollars per ton of NOx emission reductions for the SoCalGas facilities we examined.

There will be cases where it will not be practical or financially viable to retrofit existing buildings with zero-emissions space and water heating equipment. Therefore, PAR 1146.2 should incorporate measures to handle situations where such equipment isn't feasible or where power supply to a facility is unavailable. In cases where installing zero-emissions units isn't feasible, transitional alternatives such as low-NOx technologies should be allowed.

Conclusion

SoCalGas appreciates the chance to provide feedback on PAR 1146.2. Prioritizing control measures that enhance reliability and resiliency will yield reductions in NOx and other criteria pollutants, including reductions in GHG. Exploring a diversified energy supply will ensure enduring and cost-effective emission reductions. SoCalGas eagerly anticipates working together to mutually pursue California's shared objectives of advancing air quality objectives.

Respectfully,

/s/ Kevin Barker

Kevin Barker
Senior Manager
Energy and Environmental Policy

RESPONSE TO COMMENT LETTER #15**Response to Comment 15-1:**

Staff appreciates SoCalGas' comments on PAR 1146.2. Please refer to Response to Comment PC-6 for the discussion on multiple units.

Response to Comment 15-2:

Staff disagrees that the *Berkeley* decision stands for the proposition that *all* regulations that relate to the natural gas use of certain consumer appliances are preempted by the EPCA. The court in the *Berkeley* case made it very clear and repeatedly emphasized that its holding is “very narrow” and is “limited” only to building codes that regulate the gas usage of certain consumer appliances. (*California Restaurant Ass’n v. City of Berkeley*, 89 F.4th 1094, 1101, 1103, 1106.) The court also expressly acknowledged that the EPCA’s preemptive scope is “not unlimited.” (*Id.* at 1103.) As Judge Baker explained in his concurrence, “EPCA preemption is unlikely to reach a host of state and local regulations that incidentally impact ‘the quantity of natural gas’ directly consumed by a [covered] product at point of use.” (*Id.* at 1117.)

The EPCA expressly preempts “regulations concerning the energy efficiency, energy use or water use” of certain appliances. (42 U.S.C. section 6297(c).) In *Berkeley*, the court held that the EPCA preempted a local building code that prohibited new buildings from connecting to the natural gas meter, effectively preventing the use of natural gas appliances covered by the EPCA in those buildings and thus reducing the natural gas use of those appliances to zero. Unlike Berkeley’s regulation, PAR 1146.2 does not ban natural gas or otherwise regulate the amount of natural gas used by the equipment subject to PAR 1146.2. This rulemaking is not any different from previous rulemakings lowering NOx emission limits of various equipment. PAR 1146.2 is technology and fuel-neutral and is focused on achieving the maximum NOx emission reductions possible. Equipment that meets the NOx emission limits, regardless of the energy source, is not prohibited by PAR 1146.2. While PAR 1146.2 may have some impact on natural gas use depending on a number of factors, including how they are designed to meet the zero-NOx emission standard and when zero-NOx natural gas technology becomes available, any such impact is incidental to the emission reduction purpose of PAR 1146.2. BAAQMD reached a similar conclusion in its response to a similar comment regarding the *Berkeley* case and EPCA preemption when it finalized its determination to submit its new zero-NOx emission rules for building appliances for inclusion in the State Implementation Plan. (Response to Comments: Submittal of Rules 9-4 and 9-6 to SIP, available at <https://www.baaqmd.gov/rules-and-compliance/rule-development/building-appliances>.)

Response to Comment 15-3:

Please refer to Response to Comment 12-2 and Response to Comment PW-2 for the discussions on trenching and additional construction cost.

Response to Comment 15-4:

Staff appreciated the meeting with SoCalGas to go through the SoCalGas cost estimation details, provide staff clarification and suggestions to adjust the estimation, and request further information. SoCalGas agreed to reevaluate the cost details and estimation, and staff will continue working with SoCalGas to identify any challenges.

COMMENT LETTER #16

남가주 한인 세탁 협회 (KDLA)

Korean Dry Cleaners & Laundry Association of Southern California

April 15, 2024

Hon. Vanessa Delgado, Chair
 South Coast Air Quality Management District Governing Board
 21865 Copley Dr.
 Diamond Bar, CA 91765

Subject: Urgent Request for Deferral of Consideration for Proposed Amended Rule 1146.2:
 Mitigating Economic Impact on Korean Drycleaners Laundry Association

Dear Chair Delgado and Esteemed Governing Board Members,

We write to you on behalf of the Korean Drycleaners Laundry Association (KDLA), representing FKDA members nationwide and KDLA members in Southern California. Urgently, we request the deferral of consideration of Proposed Amended Rule 1146.2. KDLA members embody the dynamic essence of an underrepresented community, along with the resilience of small businesses that form the cornerstone of Southern California's economy.

16-1

Our primary concern revolves around the lack of outreach and awareness regarding PAR 1146.2. Many members only recently became aware of this rulemaking have significant concerns regarding its potential economic impacts and feasibility. We fear the potential consequences this rule could have on the economic viability of the minority community, KDLA and related businesses.

The implementation of PAR 1146.2 poses an existential threat to numerous KDLA members, potentially driving them out of business. The financial burden imposed by mandatory upgrades and retrofits could prove insurmountable for these small businesses, which are already grappling with the devastating economic impacts of the COVID-19 pandemic. Approximately 30% of Korean American cleaners in Southern California have already closed their doors due to the pandemic's repercussions. The additional costs associated with compliance could make this situation even worse, leading to further closures, job losses, and economic instability within our community and the state of California.

16-2

Moreover, PAR 1146.2 risks triggering a ripple effect throughout the local economy by imposing substantial financial burdens on property owners and managers. Increased utility expenses and the need for rent hikes to offset compliance costs would place additional strain on tenants, further dampening consumer spending and exacerbating economic challenges in our region. Furthermore, the potential closure of KDLA would not only eliminate vital employment opportunities but also erode the cultural fabric and social cohesion of our communities.

16-3

In light of these pressing concerns, we urgently request the SCAQMD Governing Board to postpone consideration of PAR 1146.2. Additionally, we implore the Board to instruct District staff to actively engage with our organization and other stakeholders to foster a comprehensive dialogue on the feasibility and economic implications of this proposed rule.

Thank you for your attention to this matter. We stand ready to collaborate with you in finding equitable and sustainable solutions that prioritize both environmental and economic resilience in our region.

Sincerely,

Yoon Dong Kim
President
Korean Drycleaners Laundry Association Southern California

RESPONSE TO COMMENT LETTER #16

Response to Comment 16-1:

Staff appreciates the comments by the Korean Dry Cleaners & Laundry Association of Southern California on PAR 1146.2. Staff contacted the California Cleaners Association in October 2023 and has been in communication with representatives of the dry cleaning industry, including a member of the Korean Dry Cleaners & Laundry Association, since February 2024. Through meetings and site visits, staff has been working with the dry cleaners to identify challenges and propose potential solutions. As detailed in Chapter 2, the following changes were made to the rule to address the dry cleaners' concerns:

- Alternative compliance option that allows up to two consecutive ~~18~~²⁴-month extensions and an additional 12 month extension when utility upgrades delay compliance with zero-emission limits;
- Alternative compliance option that allows for an 18-month extension when construction is required to expand the space designed to house or relocate the unit and associated equipment necessary for operating the unit;
- Alternative compliance option that allows for a 6-month rental unit for emergency replacement when an owner or operator requires a short-term replacement due to sudden unit failure;
- Alternative compliance option that allows an extension of up to 24 months for a property under lease;
- Exemption for small businesses where existing units can be operated until their natural replacement after the applicable Table 3 compliance date; and
- Extended compliance date (i.e., 2033 for existing buildings) for boilers operated by dry cleaners, which are categorized as high temperature units.

Response to Comment 16-2:

Staff acknowledges some zero-emission technologies have higher upfront costs, but as zero-emission technologies become more mature and widely adopted in the market, there will be less upfront cost impact. In addition, staff is projecting lifetime utility savings based on future projected natural gas and electricity prices. The cost to operate heat pumps is lower than most electric appliances because they are so energy efficient; over the lifetime of the unit, that initial cost increase could be recovered. In addition, there are federal, state, and local incentive funding specifically to incentivize the switch to zero-emission technologies such as heat pumps. South Coast AQMD is developing a rebate program to help lower the cost for some consumers and small businesses and will be centralizing information for incentive and financing opportunities offered by other agencies and organizations.

Staff proposed several alternative compliance options as explained above and detailed in Chapter 3 that dry cleaners would be able to utilize. Staff will continue to monitor all the challenges for zero-emission implementation and will conduct a technology check-in and report the findings to the Stationary Source Committee by June 1, 2027, before the compliance dates for the high temperature units go into effect.

Response to Comment 16-3:

Staff recognizes the need to pursue emission reduction to address the air quality needs of the South Coast AQMD and also to send a market signal to manufacturers ahead of future implementation dates. Staff continues to communicate with representatives of the dry cleaning industry to discuss challenges PAR 1146.2 may pose to their operations.

Re: Regulatory Flexibility Group Comments on Proposed Amended Rule 1146.2

Dear Mr. Krause and Ms. Farr:

We write on behalf of our client the Regulatory Flexibility Group (“RFG”) regarding Proposed Amended Rule 1146.2 (“PAR 1146.2”). The RFG is an industry coalition that includes companies in the refining, utility and aerospace sectors that operate facilities within the jurisdiction of the South Coast Air Quality Management District (“SCAQMD” or the “District”) that will be affected by PAR 1146.2.

We appreciate the work that Staff has done so far to incorporate stakeholder feedback into PAR 1146.2, and we are thankful for the opportunity to comment on the proposed amendments and rulemaking process. We write to raise concerns with the legality of a ban on natural gas-fired water heaters, the sufficiency of the current cost-effectiveness analysis, the lack of environmental analysis under the California Environmental Quality Act (“CEQA”), and the ability of the electrical grid to handle PAR 1146.2’s wide-scale electrification. We also propose extending the timeline for PAR 1146.2 implementation in order to accommodate needed infrastructure upgrades, and for RECLAIM and former RECLAIM facilities to replace existing units. Each issue is discussed below.

PAR 1146.2 Effectively Bans Energy Policy and Conservation Act Covered Products

The Energy Policy and Conservation Act (“EPCA”) preempts any “State regulation concerning the... energy use... of [a] covered product.”¹ EPCA defines “energy use” as “the quantity of energy directly consumed by a consumer product at point of use.”² The Ninth Circuit recently interpreted EPCA preemption in the context of a City of Berkeley building code ordinance

¹ 42 U.S.C. § 6297(c).

² *Id.* § 6291(4).

17-1

May 3, 2024
Page 2

LATHAM & WATKINS LLP

17-1

that banned installation of natural gas piping in new construction, invalidating the ordinance as preempted by EPCA.³ While the case concerned the legality of Berkeley's ordinance and the application of EPCA preemption to building codes,⁴ the court's reasoning indicates that EPCA preemption likely also applies to a ban on natural gas appliances, such as water heaters and pool heaters, that are "covered products" under EPCA.⁵

In reaching the conclusion that EPCA preempted Berkeley's ordinance, the Ninth Circuit reasoned:

"EPCA preempts regulations... that relate to 'the quantity of [natural gas] directly consumed by' certain consumer appliances at the place where those products are used.... EPCA is concerned with the end-user's ability to *use* installed covered products at their intended final destinations, like restaurants. After all, a building code that prohibits consumers from using natural gas-powered appliances in newly constructed buildings necessarily regulates the "quantity of energy directly consumed by [the appliances] at point of use.... *In other words, a regulation on 'energy use' fairly encompasses an ordinance that effectively eliminates the 'use' of an energy source.*"⁶

PAR 1146.2, by mandating the installation of zero-emission equipment after the applicable effective date, effectively eliminates the use of an energy source (natural gas) for these EPCA-covered appliances. Accordingly, PAR 1146.2 falls squarely within the scope of the Ninth Circuit's EPCA preemption analysis. "Put simply, by enacting EPCA, Congress ensured that the States and localities could not prevent consumers from using covered products in their homes, kitchens, and businesses."⁷ EPCA therefore preempts PAR 1146.2.

The Cost-Effectiveness Analysis Excludes Substantial Costs

17-2

We appreciate that Staff has updated its cost-effectiveness analysis throughout the rulemaking process. We note, however, that the most recent analysis does not include the substantial costs associated with the on-site electrical infrastructure upgrades necessary to transition to zero-emissions technology at many facilities, particularly at facilities with multiple units subject to PAR 1146.2, spread across many buildings.

³ *California Restaurant Association v. City of Berkeley* (9th Cir. 2024) 89 F.4th 1094, 1098.

⁴ *Id.* at 1101.

⁵ See 42 U.S.C. §§ 6292(a) (covered products include water heaters and pool heaters). EPCA preemption also extends to certain industrial equipment. 42 U.S.C. § 6316(a). See also 88 Fed. Reg. 69686 (Oct. 6, 2023) (establishing standards for commercial water heating equipment).

⁶ *California Restaurant Association*, 89 F.4th at 1101–02.

⁷ *Id.* at 1103.

May 3, 2024
Page 3

LATHAM & WATKINS LLP

17-2

Other than the potential need for an electrical panel upgrade, Staff's analysis regarded the difference in installation costs between natural gas-fired and zero-emission units to be negligible.⁸ This is a vast underestimation. Staff's assumption fails to appropriately consider the cost of the electrical infrastructure design, engineering, and installation that is necessary to support the installation and operation of zero-emissions units at a facility. Such infrastructure upgrades depend on the specifics of each facility and may include replacement of air handlers, installation of new switch gears, seismic building upgrades, and *even new electrical substations to handle increased electricity demand*. For larger facilities, these infrastructure upgrades could result in facilities expending tens of millions of dollars (if not more) to comply with PAR 1146.2 requirements. As detailed fully in a comment letter submitted by RFG member SoCalGas,⁹ this is a substantial cost that is unique to the deployment of zero-emissions units, making the cost of installing zero-emission units significantly higher than the costs associated with replacing natural gas-fired units with like units. Specifically, SoCalGas calculated a multi-unit installation scenario and concluded that replacing five natural gas-fired units with zero-emission units would be over \$1.8 million more expensive than replacing the natural gas-fired units with like units. This incremental cost increase will quickly compound to substantial capital outlays for facilities that must replace many units and for entities with multiple facilities. These costs must be considered in order to conduct an accurate cost-effectiveness analysis.

The Cost-Effectiveness Exceeds Screening Thresholds

17-3

The 2022 Air Quality Management Plan ("AQMP") adopted a cost-effectiveness threshold of \$325,000 per ton of NO_x reduced, which was updated to \$349,000 to reflect 2022 dollars for the PAR 1146.2 rulemaking.¹⁰ Pursuant to the AQMP, when the cost-effectiveness threshold is exceeded, District Staff must hold a public meeting to discuss "emission standards with a cost-effectiveness at or below the proposed screening threshold and/or compliance or implementation options to address an emission standard that is above the proposed screening threshold."¹¹ Further, at the public hearing for the proposed amendments, Staff must present the various emission standard options and the emission reductions associated with each.¹²

The most recent cost-effectiveness figures calculated by Staff exceed the screening threshold for Type 1 High Temperature Units.¹³ When including the costs associated with electrical infrastructure design, engineering, and installation, SoCalGas' analysis confirms that the cost-effectiveness for replacement of all unit categories will greatly exceed the screening threshold.¹⁴ For example, when considering all installation costs, the cost-effectiveness of replacing a Type 1 water heater with a heat pump water heater is over \$3 million per ton of NO_x

17-3

reduced, and the cost-effectiveness of replacing a Type 2 boiler with a heat pump water heater is over \$2.5 million.¹⁵ Staff must adhere to the public process outlined in the 2022 AQMP before bringing PAR 1146.2 to the Board for a public hearing.

PAR 1146.2 Requires Additional CEQA Analysis

17-4

We are concerned that the District's decision not to prepare additional environmental analysis for PAR 1146.2 may run afoul of CEQA. The scope of the proposed amendments in PAR 1146.2 is greater than the project descriptions of the relevant control measures analyzed in the Final Program Environmental Impact Report for the 2022 AQMP ("2022 AQMP PEIR"). While the analysis of control measure C-CMB-01 in the 2022 AQMP PEIR appears to encompass the replacement of Type 1 and Type 2 water heaters subject to PAR 1146.2, the scope of the project has changed substantially in regard to replacement of instantaneous water heaters and Type 1 pool/spa heaters.

Specifically, control measure C-CMB-01 was analyzed to include the replacement of 64,000 Type 1 and 32,000 Type 2 water heaters,¹⁶ but there appears to be no analysis for the 300,000 instantaneous water heaters that Staff estimates will be subject to replacement under PAR 1146.2.¹⁷ Additionally, control measure R-CMB-04, which includes replacement of pool heaters with zero-emission technology, analyzed replacement of only 200,000 pool heaters¹⁸ while Staff estimates that PAR 1146.2 will apply to 708,000 units.¹⁹

Beyond the substantial increase in the number of affected sources, the District continues to vastly underestimate the on-site infrastructure upgrades that will be required to install PAR 1146.2-required units. Replacing natural gas-fired boilers with zero-emission units requires replacing the associated infrastructure as well, particularly at larger facilities. Most notably, some facilities will need to construct new substations to support the electrical needs of PAR 1146.2-required units. Existing electrical supplies are already strained to accommodate planned facility growth and other in-process electrification efforts such as installing electric vehicle charging infrastructure. Other infrastructure upgrades may also be necessary, for example:

- Replacing a boiler can also require replacing associated air handlers, and facilities with many boilers may have scores of air handlers to replace.
- At facilities with boilers spread across multiple buildings, new switch gears will need to be installed in each building.
- Seismic upgrades may be necessary when equipment is installed on the roofs of buildings because heat pumps and associated equipment can be considerably heavier than natural-gas fired equipment.

LATHAM & WATKINS LLP

17-4

Staff has concluded that the 2022 AQMP PEIR “adequately describes the activities associated with implementing PAR 1146.2 for the purposes of CEQA” and that PAR 1146.2 is a “later activity” within the scope of the 2022 AQMP PEIR.²⁰ However, the project changes described above may lead to different effects or more severe effects than those analyzed in the 2022 AQMP PEIR. Further, the on-site infrastructure upgrades needed to install zero-emissions units at larger facilities greatly exceed what the District has acknowledged to date, and the impacts from that construction were not considered in the 2022 AQMP PEIR. Accordingly, further environmental analysis is required to comply with CEQA.²¹ Prior to considering the rule for adoption, the District should conduct a subsequent environmental analysis of PAR 1146.2 and release the resulting document for public comment.

17-5

The Compliance Dates Should be Extended to Allow Time for Infrastructure Upgrades and Development of a Robust Supply Chain

As discussed above, replacement of natural gas water heaters with electric units will require significant infrastructure upgrades at many facilities. This will take both significant time and require significant capital outlay. Implementation of PAR 1146.2 on the currently proposed timeline may therefore cause facilities to forgo growth opportunities and have the effect of slowing the progress of other important electrification initiatives in order to meet PAR 1146.2 compliance deadlines. Additionally, we are concerned that the proposed compliance timelines do not adequately account for the needed ramp up in manufacturing and supply chains sufficient to provide the electric units that facilities will need in order to comply with the rule. Facilities will be unable to maintain compliance if supply is not sufficient and may be forced to incur inflated costs in order to obtain units that are in short supply. *For all of these reasons, we propose that the compliance dates in PAR 1146.2, Table 3 each be extended ten years.*

17-6

We Are Concerned with the Grid’s Ability to Handle the Transition

Implementation of PAR 1146.2 will significantly increase the load on the power grid. As RFG raised in letters commenting on the 2022 AQMP, the electrification measures proposed in the 2022 AQMP will require increased electrical generation and development of associated infrastructure. The increased load on the grid could adversely impact the affordability, availability, and reliability of the regional energy market. Further, there are significant cost and timing challenges associated with the deployment of needed infrastructure, including likely delays driven by strategic litigation brought under CEQA. Increased litigation risk may discourage investments from public utilities and private parties that are necessary to realize a resilient and reliable grid that can handle the wide-scale deployment of zero-emission technologies. These challenges are yet to be solved and may threaten the ability for facilities to implement wide-scale electrification measures like those contemplated by PAR 1146.2.

²⁰ SCAQMD, PAR 1146.2 Stationary Source Committee Presentation (March 15, 2024), p. 13.

²¹ See Cal. Code Regs. tit. 14, § 15168(c)(1) (“If a later activity would have effects that were not examined in the program EIR, a new initial study would need to be prepared leading to either an EIR or a negative declaration.”); see also Cal. Code Regs. tit. 14, § 15162(a)(1) (subsequent EIR required when “[s]ubstantial changes are proposed in the project which will require major revisions of the previous EIR or negative declaration due to the involvement of new significant environmental effects or a substantial increase in the severity of previously identified significant effects.”)

May 3, 2024
Page 6

LATHAM & WATKINS LLP

17-6

As discussed above, proposed amendments in PAR 1146.2 will prompt electrification on a scale even more expansive than contemplated in the relevant 2022 AQMP control measure. The resulting environmental effects of the expanded scope of electrification driven by PAR 1146.2 must be carefully considered and fully understood prior to the adoption of the rule to avoid unintended consequences.

17-7

It is not Feasible for RECLAIM and Former RECLAIM Facilities to Replace Certain Existing Boilers Within One Year of Rule Adoption

Another area of concern is the requirement that RECLAIM and former RECLAIM facilities replace existing units that do not meet specific NOx limits within one year of rule adoption. Specifically, effective one year after rule adoption, PAR 1146.2 paragraph (d)(9) prohibits current and former RECLAIM facilities from operating Type 2 units manufactured prior to January 1, 2010 that do not meet NOx emission limits of 30 ppmv and Type 1 units manufactured prior to January 1, 2012 that do not meet NOx emission limits of 55 ppmv. One year is not sufficient time for the required design, planning, engineering, permitting, and infrastructure upgrades necessary to replace these units with zero-emissions units. To facilitate a successful transition, we propose that current and former RECLAIM facilities be given three years to phase these units out.

Conclusion

We greatly appreciate the opportunity to provide these comments on PAR 1146.2. We would also appreciate a meeting to discuss the concerns expressed in this letter. Please contact me at (213) 891-7395, or by email at john.heintz@lw.com with your availability to schedule a discussion.

Best regards,

John C. Heintz

RESPONSE TO COMMENT LETTER #17**Response to Comment 17-1:**

Staff appreciates the comments by the Regulatory Flexibility Group. Please see Response to Comment 15-2 regarding EPCA preemption.

Response to Comment 17-2:

The cost-effectiveness analysis for BARCT is to evaluate the incremental cost per ton of emission reductions by retrofitting or replacing a type of equipment with newer technologies. This analysis is equipment based, and it considers incremental installation and electrical upgrade costs as explained in Chapter 2 of this staff report. Although the cost-effectiveness does not evaluate the total cost for a facility with multiple units, the socioeconomic impact analysis for this project assesses the total cost impact for the region.

Please see Response to Comment 5-3 regarding incremental installation cost and Response to Comment 12-2 regarding the cost of multiple unit replacement and potentially required electrical infrastructure construction (e.g., trenching).

Staff met with SoCalGas to go through the SoCalGas cost estimation details, provided staff clarification and suggestions to adjust the estimations, and requested further information. As noted in Response to Comment 15-4, SoCalGas agreed to reevaluate the cost details and estimation. Staff will follow up with SoCalGas for their updated cost estimation.

Response to Comment 17-3:

For PAR 1146.2, staff did not identify multiple control options that would meet the air quality objectives. The 2022 AQMP's objective is to transition to zero-emission technologies, wherever feasible, and staff identified technically feasible zero-emission control options for each category of equipment subject to Rule 1146.2.

Staff understands the cost-effectiveness for Type 1 high temperature units is over the 2022 AQMP cost-effectiveness threshold, and thus proposed later implementation dates for high temperature units, which are 2029 for installations in new buildings and 2033 for installations in existing buildings. In addition, staff has committed to conducting a technology check-in by June 1, 2027, prior to the implementation dates for high temperature units. The technology check-in will reassess the costs and cost-effectiveness to transition high temperature units to zero-emissions and may recommend changes to the emission limits or compliance schedule at that time. Establishing the zero-emission limits at this time is important to set the market signal that will drive technology development and reduce costs overtime. A public process will be included as part of the technology check-in.

Staff did not apply the installation costs suggested by SoCalGas to the installation of all units subject to PAR 1146.2. All installations will have unique challenges, as some costs might be higher than the staff's estimates and some might be lower. Overall, our cost-effectiveness approach is balanced and resulted in one category, Type I high temperature units, being over the cost screening threshold. Staff discussed the cost effectiveness of that category in several public Working Group Meetings and at Stationary Source Committee meetings. Page 4-83 of the 2022 AQMP requires discussing at public meetings, "other

emission standards with a cost-effectiveness at or below the proposed screening threshold **and/or** compliance **or** implementation options to address an emission standard that is above the proposed screening threshold." (Emphasis added.) The approach staff has discussed in public meetings, presented to the Stationary Source Committee, and will present at the Public Hearing, is the implementation approach to allow for an extended compliance schedule for high temperature units, coupled with the technology check-in to reassess costs. In addition, the rule includes a number of alternative compliance options designed to address potential challenges and costs for the transition to zero-emission technologies. Finally, the average cost-effectiveness of PAR 1146.2 when considering the entire rule universe is about \$137,000 per ton of NO_x reduction, which is well below the 2022 AQMP cost-effectiveness screening threshold.

Response to Comment 17-4:

The Final Program EIR for the 2022 AQMP extensively analyzes a full suite of control measures that were adopted in the 2022 AQMP, including Control Measure C-CMB-01 upon which PAR 1146.2 relies. Appendix A of this staff report provides the evidence which explains how implementation of PAR 1146.2 comports with the analysis in the Final Program EIR for the 2022 AQMP relative to implementing Control Measure C-CMB-01. In particular, Table A-1 contains a summary of the conclusions for the environmental topic areas with potentially significant impacts in the Final Program EIR for the 2022 AQMP which are specific to implementing Control Measure C-CMB-01 (see Appendix A of this staff report, p. A-6). Further, Table A-2 (see Appendix A of this staff report, p. A-7) summarizes the physical changes expected, environmental topic areas affected, and the applicable mitigation measures associated with implementation of PAR 1146.2 and compares the similarities to those analyzed for Control Measure C-CMB-01 in the Final Program EIR for the 2022 AQMP. The replacement of existing water heating equipment is expected to occur at the end of unit age. Regarding instantaneous water heaters, they are predominantly installed in residential settings which will undergo natural replacement, such that operators will remove the existing equipment and install a new water heating system, including the estimated 300,000 potential new instantaneous water heaters, regardless of implementation of PAR 1146.2. Thus, the replacement of water heaters is not considered a new impact.

Further, the replacement of existing water heating equipment is, in some cases, expected to require upgrades to electrical panels and other building components to enable the increased use of zero-emission equipment. Therefore, of the physical changes contemplated from Control Measure C-CMB-01, implementation of PAR 1146.2 is primarily expected to result in the increased use of electricity and natural gas to produce electricity.

It is important to note that PAR 1146.2 includes long implementation timeframes; therefore, when examining the peak daily impacts of the rule during construction and operation, whether replacing water heaters, pool heaters, or boilers and modifying the infrastructure accordingly the conclusions in the Final Program EIR for the 2022 AQMP are not anticipated to change.

Specific to the remark regarding the potential increase from 200,000 pool heaters to 708,000 pool and spa heaters, the energy estimates were updated accordingly and the

potential increase in energy usage was less than one percent, which is the criteria relied upon to determine whether the change is significant for energy use. For this reason, the change in the overall number of potential pool heater replacements over time was not considered significant new information. The details of the reasoning behind this conclusion can be found in Appendix A of this staff report (see pp. A-10 through A-11).

Finally, there is no other new additional detailed information currently available to further refine the analysis beyond what was conducted in the Final Program EIR for the 2022 AQMP for industrial facilities and CEQA does not require speculation [CEQA Guidelines Section 15145]. Of course, at the time when large industrial facilities are ready to modify their equipment to replace their units with zero-emission technology, modifications to the facility's air permits will be required and the application(s) seeking the necessary modifications will be required to undergo a project-level CEQA review at that time.

Response to Comment 17-5:

Staff has worked with stakeholders on the proposed implementation dates throughout the rulemaking process and made adjustments accordingly. Response to Comment 1-4 is an example of the adjustment of implementation dates for several categories. Staff understands an infrastructure upgrade may be needed for some existing buildings, and thus [proposes to provide an 18-month extension for construction or relocation needed and increase the extension allowance for utility upgrades from two 18-month extensions to a total of 60 months of extensions, to provide more time in these situations. Further, staff](#) has proposed more time for implementation in existing buildings versus in new buildings. For installations in existing buildings, the earliest implementation is phase one by January 1, 2029, for smaller units that have mature zero-emission technology market adoption, and a later implementation is phase three by January 1, 2033, for high temperature units. This implementation schedule provides time for owners or operators to prepare for any future installation and sends a market signal to manufacturers for more product development. Zero-emission units are available now and have been available for a long time. Staff met with appliance manufacturers who are increasing production. Further, the South Coast AQMD needs these emission reductions to achieve the NAAQS ozone and PM standards and cannot extend the compliance dates 10 years beyond what is being proposed and still achieve the NAAQS standards.

Staff will continue to monitor all the challenges for zero-emission implementation and will conduct a technology check-in and report the findings to the Stationary Source Committee by ~~January 1, 2028~~ [June 1, 2027](#), prior to the compliance dates for installations in existing buildings.

Response to Comment 17-6:

Regarding electric grid capacity and supply, please see Response to Comment 4-1 which provides staff response to a similar comment and Chapter 2 in this staff report for further discussion.

Response to Comment 17-7:

Staff removed the lower NO_x requirements previously proposed in paragraph (d)(9) and added an exception for units at RECLAIM and former RECLAIM facilities to paragraph (d)(6). This proposal revision means RECLAIM and former RECLAIM facilities will be subject to paragraph (d)(3) of PAR 1146.2 for zero-emission requirements once the existing units reach their unit age on and after the applicable Table 3 compliance dates. Please see Response to Comment 11-2 regarding the proposal revision for units in RECLAIM and former RECLAIM facilities.

EXECUTIVE SUMMARY

On March 17, 1989, the South Coast Air Quality Management District (South Coast AQMD) Governing Board adopted a resolution which requires an analysis of the economic impacts associated with adopting and amending rules and regulations. In addition, Health and Safety Code Section 40440.8 requires a socioeconomic impact assessment for any proposed rule, rule amendment, or rule repeal which “will significantly affect air quality or emissions limitations.” Lastly, Health and Safety Code Section 40920.6 requires an incremental cost-effectiveness analysis for a proposed rule or amendment which imposes Best Available Retrofit Control Technology (BARCT) or “all feasible measures” requirements relating to emissions of ozone, carbon monoxide (CO), sulfur oxides (SOx), nitrogen oxides (NOx), volatile organic compounds (VOC), and their precursors.

Proposed Amended Rule (PAR) 1146.2– Control of Oxides of Nitrogen from Large Water Heaters, Small Boilers and Process Heaters was developed to seek further emission reductions of NOx from natural gas-fired equipment within the South Coast AQMD’s jurisdiction and implement the 2022 Air Quality Management Plan (AQMP) Control Measure C-CMB-01: Emission Reductions from Replacement with Zero-emission or Low NOx Appliances – Commercial Water Heating. Upon full implementation, PAR 1146.2 is expected to reduce NOx emissions by 5.6 tons per day (tpd).

A socioeconomic impact assessment has been conducted to assess the cost impacts of PAR 1146.2 and the following presents a summary of the analysis and findings.

Key Elements of PAR 1146.2 PAR 1146.2 requires zero-emission technologies at future effective dates for natural gas-fired large water heaters, small boilers, and process heaters with a heat input greater than 75,000 British thermal units per hour (Btu/hr) and less than or equal to 2 million Btu per hour (MMBtu/hr).

Affected Facilities and Industries PAR 1146.2 is applicable to manufacturers, distributors, retailers, resellers, installers, owners, and operators of natural gas-fired large water heaters, small boilers, and process heaters with a heat input rating between 75,000 Btu/hr and 2 MMBtu/hr. PAR 1146.2 does not regulate residential gas-fired tank type water heaters rated less than 75,000 Btu/hr heat input. However, residential instantaneous water heaters and pool heaters are regulated by Rule 1146.2 due to higher Btu ratings of those type of units. The PAR 1146.2 universe is comprised of approximately 1,070,000 units of water heaters, high temperature units and pool heaters, which are used in residential, commercial, or light industrial settings. Nearly all industries will be affected by PAR 1146.2. Specifically, the warehousing and storage sector (NAICS 493) will be most affected by PAR 1146.2, followed by sectors of nursing and residential care facilities (NAICS 623) and museums, historical sites, and similar institutions (NAICS 712). Prior analyses in South Coast AQMD indicate that most of the facilities in these sectors do not qualify as a small business pursuant to South Coast AQMD Rule 102 – Definition of Terms. Due to insufficient data on the universe of the facilities affected by PAR 1146.2, a full-blown small business impact analysis is not feasible for this socioeconomic impact assessment.

Assumptions for the Analysis

Most of the compliance costs of PAR 1146.2 are related to the transition from gas-fired to zero-emission water heating equipment. Cost estimation involves an estimated universe of 1,070,000 units of Type 1 and Type 2 units, tank type or instantaneous water heaters, high temperature units and pool heaters, 90 percent (%) of which are assumed to be replacement of old gas-fired units in existing commercial, residential, or light industrial buildings, while the remaining 10% are first-time installations in new buildings for the applicable category pursuant to PAR 1146.2 paragraph (d)(2) on and after the applicable PAR 1146.2 compliance dates.

The analysis assumed the unit age of all existing units is uniformly distributed over a period of their full useful life, implying that implementing PAR 1146.2 at the existing buildings will be a linear, phased-in process. After the phase-in is completed, all of the old gas-fired units will have been replaced by zero-emission units. In addition, PAR 1146.2 provides an implementation grace period for existing buildings, that is, the first year of implementation is allowed to occur three or four years later than what is required for new buildings. Equipment replacement occurring in existing buildings may involve an electric panel upgrade cost, while installing zero-emission units in new buildings has no such upgrade cost.

To estimate the fuel switching cost/saving of transitioning from natural gas to zero-emission water heating technologies that use electricity, this analysis considered the anticipated energy demand and forecasted prices in the future for both natural gas and electricity. The source of the forecasted energy prices is the 2023 California Energy Commission (CEC) Integrated Energy Policy Report (IEPR). For Type 1 pool heaters and instantaneous water heaters, residential utility rates are applied, while commercial utility rates are applied for all the other categories of units. In addition, the CEC IEPR considers three different scenarios: a baseline scenario, a high energy demand scenario and a low energy demand scenario. The analysis in this report applied the electricity price forecast from the baseline scenario.

Compliance Costs

The average annual compliance costs of PAR 1146.2 are estimated to range from \$48.99 million to \$96.77 million, depending on the real interest rate assumed (1% to 4%). The estimated annual costs are expected to be incurred by nearly all the industries in the South Coast AQMD region.

The following table presents the summary of the average annual cost of PAR 1146.2 by equipment category. Except for instantaneous water heaters, all the equipment categories exhibit a cost savings in their recurring fuel-switching cost. With one-time and recurring costs combined, about 32% of the total annual compliance cost is attributed to

Type 2 water heaters being replaced with two split heat pumps, followed by instantaneous water heaters which would be about 21% of the total annual cost.

Average Annual Compliance Costs (2026-2057)

Cost Categories	1% Real Interest Rate	4% Real Interest Rate
One-Time Cost		
Type 1 Water Heater replaced by heat pump	\$16,289,888	\$19,728,126
Type 1 High Temperature Unit replaced by heat pump	\$8,260,714	\$11,309,575
Type 2 Water Heater - Scenario with replacement by two split heat pumps	\$32,344,304	\$44,281,929
Type 2 High Temperature Unit replaced by heat pump	\$6,294,343	\$8,617,457
Type 1 Pool Heater replaced by heat pump	\$121,291,936	\$146,892,519
Instantaneous Water Heater replaced by heat pump	\$3,847,000	\$5,266,850
Recurring Costs		
Type 1 Water Heater replaced by heat pump	(\$2,671,829)	(\$2,671,829)
Type 1 High Temperature Unit replaced by heat pump	(\$4,376,038)	(\$4,376,038)
Type 2 Water Heater - Scenario with replacement by two split heat pumps	(\$12,786,700)	(\$12,786,700)
Type 2 High Temperature Unit replaced by heat pump	(\$4,819,582)	(\$4,819,582)
Type 1 Pool Heater replaced by heat pump	(\$129,540,284)	(\$129,540,284)
Instantaneous Water Heater replaced by heat pump	\$14,865,970	\$14,865,970
Total	\$48,999,721	\$96,767,993

Job Impacts

Direct effects of the proposed project are used as inputs to the REMI model in order for the model to assess secondary/induced impacts for all the industries in the four-county economy on an annual basis and across a user-defined horizon.

When the compliance cost is annualized using a 4% real interest rate, it is projected that an annual average of 1,074 net jobs will be foregone from 2026 to 2057. The 1,074 annual jobs foregone represents approximately 0.0084% of total annual jobs in the four-county area.

In 2031, about 600 additional jobs are projected to be added to the economy due to the compliance expenditures and additional spending associated with the installation of zero-emission water heaters. These additional jobs are expected to come from sectors such as retail (NAICS 44-45), fabricated metal product manufacturing (NAICS 332), and wholesale trade (NAICS 42).

However, as affected facilities continue to bear the amortized capital expenditures of zero-emission water heaters, a gradual reduction in the positive job impacts from earlier years is expected to occur. Consequently, this reduction would lead to jobs foregone in the subsequent years following the initial implementation.

The construction sector (NAICS 23) is anticipated to bear the largest share of average annual jobs foregone, with an estimated 173 jobs foregone.

Competitiveness

The overall impacts of the PAR 1146.2 on the production costs and delivered prices in the region is not expected to be significant. According to the REMI Model, PAR 1146.2 is projected to increase the cost of production of all the industries in South Coast AQMD's jurisdiction by 0.002% and increase the relative delivered price of the goods provided by those industries by 0.002% in 2032, when PAR 1146.2 has the greatest impacts upon cost of production and relative delivered price in affected industries.

INTRODUCTION

Rule 1146.2– Control of Oxides of Nitrogen from Large Water Heaters, Small Boilers and Process Heaters, regulates NOx emissions from natural gas-fired large water heaters, small boilers, and process heaters with a heat input greater than 75,000 Btu/hr and less than or equal to 2 MMBtu/hr. Rule 1146.2 was adopted in January 1998 and last amended in 2018.

Proposed Amended Rule (PAR) 1146.2 seeks further NOx emission reductions from natural gas-fired equipment in South Coast AQMD’s jurisdiction and implements the 2022 AQMP Control Measure C-CMB-01: Emission Reductions from Replacement with Zero-emission or Low NOx Appliances – Commercial Water Heating. Upon full implementation, PAR 1146.2 is expected to reduce NOx emissions by 5.6 tpd.

The provisions of PAR 1146.2 are applicable to manufacturers, distributors, retailers, resellers installers, owners, and operators of natural gas-fired large water heaters, small boilers, and process heaters less than or equal to 2 MMBtu/hr. PAR 1146.2 does not regulate residential gas-fired tank type water heaters less than 75,000 Btu/hr heat input which are regulated under South Coast AQMD Rule 1121 – Control of Nitrogen Oxides from Residential Type, Natural Gas-Fired Water Heaters (Rule 1121); however, residential instantaneous (tankless) water heaters and pool heaters are regulated by Rule 1146.2 due to the higher Btu ratings of those type of units. Units used in recreational vehicles are exempt from the requirements of Rule 1146.2.

PAR 1146.2 will affect approximately 1,070,000 units in the South Coast AQMD, including approximately 710,000 pool heaters, 300,000 instantaneous water heaters, and 60,000 other Type 1 and Type 2 units. Type 1 units are the units with rated heat input capacity less than or equal to 400,000 Btu/hr, and Type 2 units are the ones sized greater than 400,000 Btu/hr and less than or equal to 2,000,000 Btu/hr.

LEGISLATIVE MANDATES

The legal mandates directly related to the assessment of PAR 1146.2 include South Coast AQMD Governing Board resolutions and various sections of the Health and Safety Code.

South Coast AQMD Governing Board Resolution

On March 17, 1989, the South Coast AQMD Governing Board adopted a resolution that calls for an economic analysis associated with adopting and amending rules and regulations that considers all of the following elements:

- Affected industries
- Range of probable costs
- Cost-effectiveness of control alternatives
- Public health benefits

Health and Safety Code Requirements

The state legislature adopted legislation which reinforces and expands the South Coast AQMD Governing Board resolution requiring socioeconomic impact assessments for rule development projects. Health and Safety Code Section 40440.8, which went into effect on January 1, 1991, requires a socioeconomic impact assessment for any proposed rule, rule amendment, or rule repeal which "will significantly affect air quality or emissions limitations."

To satisfy the requirements in Health and Safety Code Section 40440.8, the scope of the socioeconomic impact assessment should include all of the following information:

- Type of affected industries;
- Impact on employment and the regional economy;
- Range of probable costs, including those to industry;
- Availability and cost-effectiveness of alternatives to the rule;
- Emission reduction potential; and
- Necessity of adopting, amending, or repealing the rule in order to attain state and federal ambient air quality standards.

Health and Safety Code Section 40728.5, which went into effect on January 1, 1992, requires the South Coast AQMD Governing Board to: 1) actively consider the socioeconomic impacts of regulations; 2) make a good faith effort to minimize adverse socioeconomic impacts; and 3) include small business impacts. To satisfy the requirements in Health and Safety Code Section 40728.5, the socioeconomic impact assessment should include the following information:

- Type of industries or business affected, including small businesses; and
- Range of probable costs, including costs to industry or business, including small business.

Finally, Health and Safety Code Section 40920.6, which went into effect on January 1, 1996, requires an incremental cost-effectiveness analysis for a proposed rule or amendment which imposes Best Available Retrofit Control Technology (BARCT) or "all feasible measures" requirements relating to emissions of ozone, carbon monoxide (CO), sulfur oxides (SO_x), nitrogen oxides (NO_x), VOC, and their precursors. The BARCT and cost-effectiveness analyses for PAR 1146.2 were conducted and are located in Chapter 2 of the Final Draft Staff Report.

AFFECTED FACILITIES AND INDUSTRIES

Water heaters, boilers, and pool heaters which are subject to PAR 1146.2 requirements can be used in residential as well as commercial and light industrial settings. Since residences are not facilities, the universe of PAR 1146.2 is based on the number of affected units (e.g., water heaters, boilers and pool heaters), instead of affected facilities. The affected units are split into two categories: Type 1 units with a rated heat input capacity less than or equal to 400,000 Btu/hr, and Type 2 units whose rated heat input capacity is greater than 400,000 Btu/hr but less than or equal to 2,000,000 Btu/hr. The total PAR 1146.2 universe is comprised of approximately 1,070,000 units, with approximately 710,000 pool heaters, 300,000 instantaneous water heaters, and 60,000 other units.

The 2019 Residential Appliance Saturation Study (RASS) finds that 7% of homes in the region where SoCalGas is the natural gas provider have gas-heated spas and 5% have pools with gas

heaters.¹ There are approximately 5.9 million homes in the South Coast AQMD region based on the U.S. Census' 2021 American Housing Survey. Thus, staff conservatively estimated that there are approximately 710,000 (calculated as 5,900,00 x 12%) Type 1 pool heaters operating at residences in the South Coast AQMD region.

The 2006 rule amendment also relied on data provided by SoCalGas which estimated that there were 40,000 and 22,000 units of Type 1 and Type 2 water heaters and boilers, respectively, in the South Coast AQMD jurisdiction at the time. For the PAR 1146.2 analysis, the analysis assumed 60,000 total units for these categories in the region. Meanwhile, the proportions of Type 1 and Type 2 units in the universe that are not Type 1 pool heaters or instantaneous water heaters was also updated utilizing the Air-Conditioning, Heating, and Refrigeration Institute (AHRI) certifications data.

Recently, the deployment of residential instantaneous water heaters has increased in response to federal and state energy efficiency regulations. Using the 2019 California Residential Appliance Saturation Study (RASS) from the CEC and the Residential Energy Consumption Survey (RECS) from the U.S. Energy Information Administration, there are approximately 300,000 instantaneous water heaters in the South Coast AQMD jurisdiction.²

Affected Industries and Small Business

PAR 1146.2 is applicable to manufacturers, distributors, retailers, installers, and operators of natural gas-fired large water heaters, small high temperature units, and process heaters less than or equal to 2 MMBtu/hr. Staff estimated a universe of 1,070,000 units of tank type/instantaneous water heaters, pool heaters, and other units. The majority of the instantaneous water heaters and pool heaters are used in residential buildings while the rest are primarily used in commercial or light industrial installations. For rental properties, the transition from gas-fired units to zero-emission equipment will increase operation costs of commercial buildings, which then could be passed on to tenants through raised rents. Nearly all industries that will be affected by PAR 1146.2 rent office space. Table 1 presents the ratio of the value of real estate usage to total output for various industries³; this ratio can be used as a proxy for the extent that the industries will be affected by increased rents due to the implementation of PAR 1146.2. As shown in Table 1, the warehousing and storage sector (NAICS 493) will be the most affected by PAR 1146.2, followed by the nursing and residential care facilities sector (NAICS 623) and the museums, historical sites, and similar institutions sector (NAICS 712). Prior analyses conducted in South Coast AQMD show that most of the facilities in these sectors do not qualify as a small business pursuant to South Coast AQMD Rule 102. However, due to the lack of data on the universe of the affected facilities and the broad scope of the proposed project, a more robust small business impact analysis is not feasible for this socioeconomic impact assessment.

¹ California Energy Commission, 2019 California Residential Appliance Saturation Study, <https://www.energy.ca.gov/publications/2021/2019-california-residential-appliance-saturation-study-rass> (please refer to Table ES-3 in Page 11)

3361-3363	Motor vehicles, bodies and trailers, and parts manufacturing	0.22%
331	Primary metal manufacturing	0.18%
113-114	Forestry and Logging; Fishing, hunting and trapping	0.17%
212	Mining (except oil and gas)	0.11%
324	Petroleum and coal products manufacturing	0.03%
115	Support activities for agriculture and forestry	0.01%

COMPLIANCE COSTS

Most of compliance costs associated with implementing PAR 1146.2 are related to the transition from gas-fired to zero-emission water heating equipment. The cost estimate relies on the estimated universe of 1,070,000 units of tank type/instantaneous water heaters, high temperature units, pool heaters, and other Type 1 and Type 2 units, 90% of which are assumed to be replacements of old gas-fired units in existing commercial or residential buildings, while the remaining 10% are first-time installations to new buildings on and after the applicable PAR 1146.2 compliance dates.

The analysis assumed the unit age of all existing units is uniformly distributed over a period of their full useful life, implying that implementing PAR 1146.2 at the existing buildings will be a linear, phased-in process. After the phase-in is completed, all of the old gas-fired units will have been replaced by zero-emission units. The analysis assumed new buildings will be built up gradually, and thus also assumed a linear phased-in process of rule implementation over the full useful life of equipment for the new buildings. In addition, PAR 1146.2 provides an implementation grace period for existing buildings, that is, the first year of implementation is allowed to occur three or four years later than what is required for new buildings. Equipment replacement occurring in existing buildings may involve an electric panel upgrade cost, while installing zero-emission units in new buildings has no such upgrade cost.

Water Heaters

Type 1 Water Heater Replaced by Heat Pump

Type 1 water heaters are gas-fired units with a heat input capacity rated less than or equal to 400,000 Btu/hr, which are expected to be replaced with zero-emission heat pump water heaters. Based on estimates in the May 2006 Final Staff Report for Rule 1146.2, on average, the purchase price of a gas-fired Type 1 water heater was approximately \$7,000 in 2023 US dollars.^{4 5} For a comparable zero-emission heat pump water heater, this analysis assumed a purchase price of \$13,200 and a panel upgrade cost of \$2,500 based on manufacturer quotes, which yields an incremental cost of \$8,700 to upgrade a Type 1 water heater in an existing building. Since no panel upgrade costs will be required in new buildings, the installation of Type 1 heat pump water heaters as part of new construction will have a lower incremental cost at \$6,200. Based on the U.S. Department of Energy (DOE) estimates and the parameters previously relied upon in Socioeconomic Impact Assessment for the 2022 AQMP, a useful life of 15 years is assumed for the heat pump water heater. The first compliance dates for new and existing buildings are January 1, 2026 and January 1, 2029, respectively.

Type 2 Water Heater Replaced with Two Split System Heat Pumps

Type 2 water heaters have a higher heat input capacity, rated between 400,000 and 2,000,000 Btu/hr. Per a manufacturer's recommendation, a 500,000 Btu/hr Type 2 natural gas water heater will be replaced by two split system heat pump water heaters with a 400-gallon tank and an estimated useful life of 25 years. Based on the May 2006 Final Staff Report for Rule 1146.2, the purchase price for a comparable high-efficiency natural gas-fired commercial tank-type unit was

⁴ Unless specified otherwise, all of the dollar amounts presented in this report will be in 2023 US dollars.

⁵ South Coast Air Quality Management District, 2006 Final Staff Report for Proposed Rule 1146.2, <http://www3.aqmd.gov/hb/2006/May/060535a.html>

approximately \$14,000 in 2023 dollars. In contrast, the anticipated capital cost for the two split system heat pumps is approximately \$84,000 with a panel upgrade cost of \$4,200, according to manufacturer quotes. Thus, the incremental capital cost per unit for this replacement is \$74,200 for existing buildings. Because no panel upgrade will be needed, the installation of Type 2 two split heat pump water heater has a lower incremental cost of \$70,000. The compliance dates for new and existing buildings are January 1, 2028 and January 1, 2031, respectively.

High Temperature Units

Type 1 High Temperature Unit Replaced by Heat Pump

Type 1 and Type 2 high temperature units are defined by the same heat input capacity criteria as the preceding Type 1 and Type 2 water heaters but are designed specifically for higher temperature applications. The incremental capital cost for Type 1 high temperature unit replacement estimate was based on a manufacturers' quotes of \$24,000 for a 399,000 Btu/hr natural gas-fired Type 1 high temperature unit, and \$222,000 for a comparable 365,000 Btu/hr heat pump unit with a \$4,200 panel upgrade cost, which yields a per-unit incremental capital cost of \$202,200 for existing buildings. Because no panel upgrade will be needed, the installation of a Type 1 heat pump high temperature unit in new buildings has a lower incremental cost of \$198,000. In addition, based on information provided by manufacturers, the analysis assumed a useful life of 25 years for the Type 1 heat pump unit. The compliance dates for new and existing buildings are January 1, 2029 and January 1, 2033, respectively.

Type 2 High Temperature Unit Replaced by Heat Pump

Manufacturer quotes were provided for a Type 2 natural gas fired high temperature unit and a comparable Type 2 heat pump unit at \$32,500 and \$336,000, respectively. The estimated panel upgrade cost for the heat pump unit is \$4,200, yielding a per-unit incremental capital cost of \$307,700 for existing buildings. Because no panel upgrade will be needed, the installation of Type 2 heat pump high temperature unit has a lower incremental cost at \$303,500 for new buildings. Again, the analysis assumed a useful life of 25 years for the Type 2 high-temperature heat pump unit. The compliance dates for new and existing buildings are January 1, 2029 and January 1, 2033, respectively.

Instantaneous Water Heater and Pool Heater Replaced with Heat Pump

Instantaneous Water Heater Replaced with Heat Pump

Instantaneous water heaters are tankless units. Based on the estimated universe of 300,000 natural gas fired instantaneous water heaters that would need to be replaced by zero-emission heat pump tank-type units, the analysis considered the replacement of a typical 150,000 Btu/hr gas-fired tankless water heater with a 65-gallon tank-type heat pump for residential applications. According to an Energy and Environmental Economics (E3) study, a 150,000 Btu/hr tankless water heater costs approximately \$2,775, while a comparable tank-type heat pump costs approximately \$2,400

based on internet quotes, resulting in potential cost savings in the purchase price.^{6, 7} However, after including the estimated panel upgrade cost of \$1,050, the per-unit incremental capital cost will be \$675 for existing buildings. In new buildings without panel upgrades, the installation of instantaneous heat pump water heater is expected to yield a per-unit cost saving at \$375 for new buildings. The analysis assumes the heat pump tank-type units have a useful life of 25 years. The compliance dates for new and existing buildings are January 1, 2026 and January 1, 2029, respectively.

Type 1 Pool Heater Replaced with Heat Pump

The last category of natural gas fired units subject to PAR 1146.2 are Type 1 pool heaters, which are specially used for heating the water in swimming pools and usually have a heat input capacity rating of less than or equal to 400,000 Btu/hr. Online quotes for pool heaters indicate that a zero-emission heat pump and a comparable traditional gas-fired heater cost \$4,920 and \$1,800, respectively. With an estimated panel upgrade cost of \$625, the per-unit incremental capital cost will be \$3,745 for existing buildings. Because no panel upgrade will be needed, the installation of a Type 1 heat pump pool heater will have a lower incremental cost at \$3,120 for new buildings. In accordance with DOE estimates, the analysis assumed a useful life of 15 years for heat pump pool heaters⁸. The compliance dates for Type 1 pool heaters are January 1, 2028 and January 1, 2031, respectively, for new and existing old buildings.

Fuel Switching Cost

The only recurring cost incurred by PAR 1146.2 is a fuel switching cost, due to the transition from natural gas fired units to zero-emission electric ones. In general, electricity is more expensive to use than natural gas; however, the higher electricity cost can be offset to some extent by the increased heating efficiency of the heat pump units.

To estimate the fuel switching cost/saving of transition from natural gas to electric water heating, the analysis considered the anticipated energy demand and forecasted prices in the future for both natural gas and electricity. The forecasted energy prices are sourced from the 2023 California Energy Commission (CEC) Integrated Energy Policy Report (IEPR).⁹ Note that CEC has a separate electricity price forecast for both the Los Angeles Department of Water and Power (LADWP) and Southern California Edison (SCE) planning areas. The analysis relied upon an average of the two forecasted prices weighted by population. Specifically, as LADWP serves

⁶ Energy and Environmental Economics, 2019 Residential Building Electrification in California, https://www.ethree.com/wp-content/uploads/2019/04/E3_Residential_Building_Electrification_in_California_April_2019.pdf. (please refer to Figure 2-7, Page 32)

⁷ Energy Star by U.S. EPA provided information on a 64-gallon storage volume heat pump with a Uniform Energy Factor of 3.64, which has a capital cost of around \$2,000 from internet search. Energy Star provides 178 therms per year for instantaneous and 1,233 kwh for an equivalent heat pump. Adding an additional 20% to the zero-emission unit cost to address installation cost results in \$2,400 for the zero-emission unit.

⁸ Energy Saver, 2024 Heat Pump Swimming Pool Heaters, <https://www.energy.gov/energysaver/heat-pump-swimming-pool-heaters>.

⁹ California Energy Commission, 2022 Integrated Energy Policy Update, Docket 22-IEPR-03 – Electricity Forecast, CEDU Baseline Forecast – LADWP, <https://efiling.energy.ca.gov/GetDocument.aspx?tn=248381&DocumentContentId=82804>, accessed February 27, 2024.

roughly 23% of the population in the region, it is assigned a weight of 0.23, while the weight of SCE is specified as 0.77. For natural gas, the analysis solely relied on Southern California Gas (SCG) company forecast, since it is the primary gas utility in the South Coast AQMD region. For Type 1 pool heaters and instantaneous water heaters, residential utility rates are used, while commercial utility rates are used for all the other categories of units. For each category of units, the steps used to estimate the recurring fuel switching cost/saving due to the transition to zero-emission units are summarized as follows:

1. Estimate daily electricity demand from the electric heat pump units;
2. Estimate daily natural gas demand of the to-be-replaced natural gas fired units;
3. Estimate annual demand of natural gas and electricity via multiplying respective daily demand by the number of operating days in a year;
4. Calculate the average price forecast for natural gas and electricity over the period 2024-2035, which is CEC forecast period;
5. Estimate annual cost of natural gas and electricity via multiplying respective annual demand by the average price forecast;
6. For each category of units, calculate annual cost difference in Step 5.

Table 2 presents annual demand and price forecast of natural gas/electricity, and calculated annual fuel switching cost/saving for each category. For a detailed description of the methods used to estimate energy inputs, please refer to Chapter 2 of the PAR 1146.2 ~~Final~~^{Draft} Staff Report.

Table 2
Annual Per-Unit Fuel Switching Cost or Saving

Equipment Type	Annual Natural Gas Demand (therms)	Annual Electricity Demand (kWh)	Forecasted Natural Gas Price (\$/therm)	Forecasted Electricity Rate (\$/kWh)	Annual Fuel Switching Cost (+) or Savings (-)
Type 1 Water Heater Replaced by Heat Pump	1,431.72	9,488.63	\$1.78	\$0.26	-\$97.82
Type 1 High Temperature Unit Replaced by Heat Pump	7,516.56	33,211	\$1.78	\$0.26	-\$4,795.66
Type 2 Water Heater Replaced by Two Split Heat Pumps	9,419.25	59,860	\$1.78	\$0.26	-\$1,305.18
Type 2 High Temperature Unit Replaced by Heat Pump	18,838	88,877	\$1.78	\$0.26	-\$10,563.47
Type 1 Pool Heater Replaced by Heat Pump	262.8	1135.15	\$2.40	\$0.31	-\$278.81
Instantaneous Water Heater Replaced by Heat Pump	177	1,646	\$2.40	\$0.31	\$85.71

It is important to note that forecasted energy prices listed in Table 2 will differ from actual observed prices. The latter are determined by many factors, including geopolitical factors, supply and demand shocks, and other unforeseeable events. In comparison, the CEC forecast is based on a rigorous modeling process that takes into account factors specific to the California utility market and reflects best available expectation of energy prices in the future.

Total Compliance Cost of PAR 1146.2

The compliance cost analysis covers the period 2026-2057. Staff first amortized one-time capital cost over the period, and then added the amortized capital cost to the recurring cost in each year to estimate annual compliance cost of PAR 1146.2. As presented in Table 3, the total present value of all the annual compliance costs is estimated at \$2,445.94 million and \$1,260.37 million, respectively, depending on the discount rate assumed (1% and 4%).¹⁰ The average annual compliance costs of PAR 1146.2 from 2026-2057 are estimated to range from \$48.99 million to

¹⁰ In 1987, South Coast AQMD staff began to calculate cost-effectiveness of control measures and rules using the Discounted Cash Flow method with a discount rate of 4%. Although not formally documented, the discount rate is based on the 1987 real interest rate on 10-year Treasury Notes and Bonds, which was 3.8%. The maturity of 10 years was chosen because a typical control equipment life is 10 years; however, a longer equipment life would not have corresponded to a much higher rate-- the 1987 real interest rate on 30-year Treasury Notes and Bonds was 4.4%. Since 1987, the 4% discount rate has been used by South Coast AQMD staff for all cost-effectiveness calculations, including BACT analysis, for the purpose of consistency.

\$96.77 million, depending on specific real interest rate assumed (1% to 4%). Except for instantaneous water heaters replaced by heat pumps, all the other equipment categories have recurring cost saving in the transition from natural-gas fired to zero-emission units.

Table 3
Total Present Worth and Average Annual Estimated Costs of PAR 1146.2

Cost Categories	Present Worth Value (2024)		Annual Average (2026-2057)	
	1% Discount Rate	4% Discount Rate	1% Real Interest Rate	4% Real Interest Rate
One-Time Cost				
Type 1 Water Heater replaced by heat pump	\$505,536,016	\$271,721,985	\$16,289,888	\$19,728,126
Type 1 High Temperature Unit replaced by heat pump	\$283,372,800	\$142,137,215	\$8,260,714	\$11,309,575
Type 2 Water Heater - Scenario with replacement by two split heat pumps	\$1,115,954,641	\$570,642,859	\$32,344,304	\$44,281,929
Type 2 High Temperature Unit replaced by heat pump	\$215,934,464	\$108,337,694	\$6,294,343	\$8,617,457
Type 1 Pool Heater replaced by heat pump	\$3,730,214,053	\$1,944,962,454	\$121,291,936	\$146,892,519
Instantaneous Water Heater replaced by heat pump	\$131,332,077	\$64,443,857	\$3,847,000	\$5,266,850

Table 3 (continued)
Total Present Worth and Average Annual Estimated Costs of PAR 1146.2

Cost Categories	Present Worth Value (2024)		Annual Average (2026-2057)	
	1% Discount Rate	4% Discount Rate	1% Real Interest Rate	4% Real Interest Rate
Recurring Costs/<i>Savings</i>				
Type 1 Water Heater replaced by heat pump	(\$68,584,256)	(\$37,093,924)	(\$2,671,829)	(\$2,671,829)
Type 1 High Temperature Unit replaced by heat pump	(\$109,668,789)	(\$55,048,647)	(\$4,376,038)	(\$4,376,038)
Type 2 Water Heater - Scenario with replacement by two split heat pumps	(\$322,404,166)	(\$165,155,913)	(\$12,786,700)	(\$12,786,700)
Type 2 High Temperature Unit replaced by heat pump	(\$120,784,537)	(\$60,628,237)	(\$4,819,582)	(\$4,819,582)
Type 1 Pool Heater replaced by heat pump	(\$3,292,841,837)	(\$1,723,007,745)	(\$129,540,284)	(\$129,540,284)
Instantaneous Water Heater replaced by heat pump	\$377,878,553	\$199,053,588	\$14,865,970	\$14,865,970
Total	\$2,445,939,019	\$1,260,365,184	\$48,999,721	\$96,767,993

Table 4 presents estimated annual compliance costs for existing and new buildings, separately. Compared with existing buildings, new buildings incur lower compliance costs as only 10% of the universe of units will be installed in the new buildings. New buildings will incur the cost earlier because of earlier compliance dates. Annual costs will also be lower for new construction due to the lack of panel upgrade costs. For example, although existing buildings incur positive annual costs for the replacement of Type 1 pool heaters, new buildings can enjoy annual cost saving due to the lack of panel upgrade cost in the installation.

Table 4
Annual and Average Annual Costs for Different Building/Unit Categories

Categories of Units	Building Type	2026	2031	2036	2057	Annual Average (2026-2057)
Type 1 Water Heater replaced by heat pump	<i>Existing</i>	\$0	\$4,477,242	\$11,939,311	\$22,386,208	\$15,390,518
Type 1 High Temperature Unit replaced by heat pump	<i>Existing</i>	\$0	\$0	\$2,203,127	\$13,769,541	\$5,593,876
Type 2 Water Heater - Scenario with replacement by two split heat pumps	<i>Existing</i>	\$0	\$2,231,089	\$13,386,533	\$55,777,222	\$26,145,573
Type 2 High Temperature Unit replaced by heat pump	<i>Existing</i>	\$0	\$0	\$1,206,066	\$7,537,912	\$3,062,277
Type 1 Pool Heater replaced by heat pump	<i>Existing</i>	\$0	\$1,914,503	\$11,487,019	\$28,717,548	\$17,948,468
Instantaneous Water Heater replaced by heat pump	<i>Existing</i>	\$0	\$4,123,222	\$10,995,258	\$34,360,180	\$18,253,846
Type 1 Water Heater replaced by heat pump	<i>New</i>	\$1,665,779	\$1,665,779	\$1,665,779	\$1,665,779	\$1,665,779
Type 1 High Temperature Unit replaced by heat pump	<i>New</i>	\$0	\$1,478,247	\$1,478,247	\$1,478,247	\$1,339,661
Type 2 Water Heater - Scenario with replacement by two split heat pumps	<i>New</i>	\$0	\$5,706,300	\$5,706,300	\$5,706,300	\$5,349,657
Type 2 High Temperature Unit replaced by heat pump	<i>New</i>	\$0	\$811,695	\$811,695	\$811,695	\$735,598
Type 1 Pool Heater replaced by heat pump	<i>New</i>	\$0	(\$635,982)	(\$635,982)	(\$635,982)	(\$596,233)
Instantaneous Water Heater replaced by heat pump	<i>New</i>	\$1,878,974	\$1,878,974	\$1,878,974	\$1,878,974	\$1,878,974
Total		\$3,544,753	\$23,651,068	\$62,122,327	\$173,453,624	\$96,767,993

Figure 1 presents the estimated annual compliance costs of the PAR 1146.2 by unit category. For each category, the figure presents the sum of the total amortized capital costs and recurring cost or savings during the period 2026-2057, for both existing and new buildings. As shown in Figure 1, Type 2 water heater replacement with two split heat pumps will incur the biggest share of average annual compliance costs (32%), followed by instantaneous water heaters (21%), Type 1 water heaters, and pool heaters (18% for each). Type 2 High Temperature Unit replaced by heat pump (4%) and Type 1 High Temperature Unit replaced by heat pump (7%) are the smallest categories.

Figure 1
Annual Estimated Costs of the PAR 1146.2 Series by Unit Categories

MACROECONOMIC IMPACTS ON THE REGIONAL ECONOMY

The Regional Economic Model (REMI, PI+ v3) was used to assess the total socioeconomic impacts of the anticipated policy change (i.e., the proposed rule).^{11, 12} The model links the economic activities in the counties of Los Angeles, Orange, Riverside, and San Bernardino, and for each county, it is comprised of five interrelated blocks: 1) output and demand; 2) labor and capital; 3) population and labor force; 4) wages, prices and costs; and 5) market shares.¹³

It should be noted that the REMI model is not designed to assess impacts on individual operations. The model was used to assess the impacts of the proposed project on various industries that make up the local economy. Cost impacts on individual operations were assessed outside of the REMI model and used as inputs into the REMI model.

Impact of Proposed Amendments

The assessment herein is performed relative to a baseline (“business as usual”) forecast where the proposed amendments would not be implemented. It is assumed that affected facilities/households would finance the capital and installation costs of control equipment, or more specifically, these one-time costs are assumed to be amortized and incurred over the equipment life. The proposed project is assumed to be the implementation of PAR 1146.2, which would create a policy scenario under which the affected facilities/households would incur an average annual compliance cost of approximately \$96.77 million when costs are annualized using a 4% real interest rate, or \$48.99 million when evaluated using a 1% real interest rate from the year 2026 onwards when all controls are assumed to have been installed.

Direct effects of the proposed project are used as inputs to the REMI model in order for the model to assess secondary and induced impacts for all the industries in the four-county economy on an annual basis and across a user-defined horizon: 2026 (the first year when the affected facilities/households are assumed to incur compliance costs due to PAR 1146.2 implementation) to 2057 (the final year in which new equipment is fully amortized). Direct effects of PAR 1146.2 include:

- 1) Additional costs that facilities would incur by installing and operating zero-emission water heaters: Because the implementation of PAR 1146.2 will affect nearly all the industries in the four-county region, all the replacement/installation and recurring costs were allocated across different industries by their value of real estate usage.¹⁴ The costs are also allocated across the

¹¹ Regional Economic Modeling Inc. (REMI). Policy Insight® for the South Coast Area (70-sector model). Version 3. 2023.

¹² REMI v3 has been updated based on The U.S. Economic Outlook for 2022-2024 from the University of Michigan's Research Seminar in Quantitative Economics (RSQE) release on May 19, 2023, The Long-Term Economic Projections from CBO (supplementing CBO's March 2023 report, The 2023 Long-Term Budget Outlook).

¹³ Within each county, producers are made up of 156 private non-farm industries and sectors, three government sectors, and a farm sector. Trade flows are captured between sectors as well as across the four counties and the rest of U.S. Market shares of industries are dependent upon their product prices, access to production inputs, and local infrastructure. The demographic/migration component has 160 ages/gender/race/ethnicity cohorts and captures population changes in births, deaths, and migration. (For details, please refer to REMI online documentation at <http://www.remi.com/products/pi>.)

¹⁴ Specifically, the value of real estate usage for each industry is estimated by the output value of the industry in the 4-county region multiplied by its value of real estate usage as a proportion of output in Table 1.

four counties by their value of total real estate usage.

- 2) Incremental costs related to replacement/installation of residential pool heaters and instantaneous water heaters which will translate into the decrease of households' disposable income: An income decrease will then have negative impact upon the local economy. This cost is allocated across the four counties by their population.
- 3) Extra demand for zero-emission water heater manufacturers and distributors, induced by the expenditure on installation and panel upgrade: In accordance with recommendations provided by representatives of REMI Inc., the induced demand is allocated to sectors of Machinery Manufacturing (NAICS 333, 40%), Fabricated Metal Product Manufacturing (NAICS 332, 20%), Miscellaneous Manufacturing (NAICS 339, 20%), Wholesale Trade (NAICS 42, 12%) and Retail Trade (NAICS 44-45, 8%).
- 4) Recurring fuel-switching cost savings, which will reduce the revenue for utility services in South Coast AQMD region.

Finally, the net increase in demand is distributed across the four counties based on their population. Table 5 summarizes the preceding setup for the REMI simulation.

Table 5
Compliance Costs and Induced Demand (Benefits) Across Industries in REMI Model

	Affected Sectors	Distribution Across Industries
Compliance Costs	All Industries	Distributed by the Value of Industries' Real Estate Usage
	Private Households	N/A
Demand Induced by:		
One-time Capital Cost	Machinery Manufacturing (NAICS 333)	40%
	Fabricated Metal Product Manufacturing (NAICS 332)	20%
	Miscellaneous Manufacturing (NAICS 339)	20%
	Wholesale Trade (NAICS 42)	12%
	Retail Trade (NAICS 44-45)	8%
Recurring Cost*	Utilities (NAICS 22)	N/A

*Recurring cost savings for PAR 1146.2.

To summarize, the direct effects of implementing PAR 1146.2 that will benefit local economy include: 1) induced demand for control equipment manufacturers and distributors; and 2) recurring cost saving of affected facilities. The direct effects that are detrimental to local economy include: 1) increased production costs of affected facilities due to installation of control equipment; 2) decreased consumption by private households; and 3) decreased demand for the Utilities sector

(NAICS 22). After that, a series of indirect or ripple effects will happen in the local economy, all of which collaboratively affect job market and competitiveness in the South Coast AQMD region, as described in the following section.

Regional Job Impacts

When the compliance cost is annualized using a 4% real interest rate, an annual average of 1,074 net jobs foregone is projected to occur from 2026 to 2057. The 1,074 annual jobs foregone represents approximately 0.0084% of total annual jobs in the four-county area.

The implementation of PAR 1146.2 is expected to have both positive and negative job impacts on the regional economy over time. In 2031, about 600 additional jobs are expected to be added to the economy due to compliance expenditures and additional spending associated with the installation of zero-emission water heaters. These additional jobs are expected to come from sectors such as retail, fabricated metal product manufacturing, and wholesale trade.

However, as affected facilities continue to bear the costs of capital expenditures, including the subsequent installation of zero-emission water heaters, the accelerated job growth due to the initial effects of equipment installation is projected to slow down, eventually leading to jobs foregone. The construction sector (NAICS 23) is anticipated to bear the largest share of average annual jobs foregone, with an estimated 173 jobs foregone. This sector is among the sectors that are expected to incur the majority of the compliance costs associated with PAR 1146.2.

The reduction in disposable income resulting from the overall jobs foregone is expected to dampen the demand for goods and services in the local economy. This, in turn, would contribute to jobs foregone in sectors such as food services and drinking places, retail trade, and ambulatory health care services. While the negative job impacts are projected to be relatively minor, several major sectors of the regional economy could experience these effects from the secondary and induced consequences of PAR 1146.2 implementation.

It is important to note that these job impact projections are based on assumptions and analysis using the REMI model. The actual job impacts may vary depending on various factors and uncertainties in the economy and industry dynamics. As presented in Table 6, many major sectors of the regional economy would experience negative job impacts in later years from the secondary and induced effects of PAR 1146.2 implementation.

Table 6
Projected Job Impacts of PAR 1146.2 for Select Industries by Year

Industry Name	2026	2031	2038	2044	2050	2057	Average Annual (2026-2057)	Baseline Average Annual (2026-2057)	Change from Baseline

Figure 2 presents a projected time series of job impacts over the 2026 - 2057 period. Based on Abt Associate's 2014 recommendation to enhance socioeconomic analysis by conducting scenario analysis on major assumptions, staff has analyzed an alternative scenario (worst case) where the affected facilities would not purchase any control equipment or services from providers within the South Coast AQMD jurisdiction.¹⁵ This is a hypothetical scenario in order to test the sensitivity of the previously discussed scenarios where the analyses rely on REMI's embedded assumptions about how the capital and O&M spending would be distributed inside and outside the region. In reality, increased manufacturing jobs related to zero-emission water heater production are likely to be offered by local equipment manufacturers.

This worst-case scenario would result in an annual average of approximately 1,602 jobs foregone. The 1,602 jobs foregone represents roughly 0.013% of total jobs in the South Coast AQMD region.

¹⁵ Abt Associates, Inc., 2014 Review of the SCAQMD Socioeconomic Assessments. Prepared for South Coast Air Quality Management District, <http://www.aqmd.gov/home/library/clean-air-plans/air-quality-mgtplan/socioeconomic-analysis>.

Figure 2
Projected Regional Job Impact, 2026-2057

Competitiveness

The additional cost brought on by PAR 1146.2 would increase the cost of services rendered by the affected industries in the region. The magnitude of the impact depends on the size, diversification, and infrastructure in a local economy as well as interactions among industries. A large, diversified, and resourceful economy would absorb the impact described above with relative ease.

Changes in production/service costs would affect prices of goods produced locally. The relative delivered price of a good is based on its production cost and the transportation cost of delivering the good to where it is consumed or used. The average price of a good at the place of use reflects prices of the good produced locally and imported elsewhere.

The overall impacts of PAR 1146.2 on the production costs and delivered prices in the South Coast AQMD region are not expected to be significant. According to the REMI Model, PAR 1146.2 is projected to increase the cost of production of all industries in the South Coast AQMD region by 0.002% and increase the relative delivered price of goods provided by those industries by 0.002% in 2032.

Proposed Amended Rule 1146.2 – Emissions of Oxides of Nitrogen from Large Water Heaters and Small Boilers and Process Heaters

Governing Board Meeting
June 7, 2024

Attachment H

Background

- PAR 1146.2 establishes zero-emission NOx standards for large residential water heaters and small commercial/industrial water heaters and boilers*
- Broad applicability
 - New and existing buildings
 - Wide range of industrial sectors and multi-family dwellings
 - Applies to approximately 1,070,000 units
- Represent almost 10 percent of stationary/area source NOx emissions regulated by South Coast AQMD

* Units less than 2 Million Btu/hour

Need for PAR 1146.2

NOx reductions needed to meet federal ozone air quality standards

Zero-emission technology is critical element of 2022 AQMP

PAR 1146.2 Implements C-CMB-01 – Commercial Water Heating in the 2022 AQMP

PAR 1146.2 Will Achieve Significant NO_x and Concurrent CO₂ Emission Reductions

~5.6 tons of NO_x emission reductions per day

- Second largest NO_x reductions (petroleum refinery rule largest)
- Reduces almost 10 percent of stationary/area source NO_x emissions regulated by South Coast AQMD
- Harmonizes with local, state, and federal decarbonization goals
 - CO₂ emission reductions equivalent to ~1.2 million vehicles

Three General Implementation Categories

**New Buildings
(Industrial, Commercial,
and Residential)**

Effective date aligned
with state building code

**Existing Commercial and
Industrial Buildings**

Longer implementation
timelines

**All Other Units (Existing
Residential Buildings)**

Replacement at natural
turnover

How Will the Rule Achieve NOx Reductions?

Earlier implementation dates for units widely commercially available and installations in new construction

Long implementation period for more challenging applications

Nine years before high temperature units **begin to transition to zero-emission**

Units transition to zero-emission if **naturally replaced** or **reach unit age**

Full transition will not occur until **2058**

Implementation Schedule for New Buildings

Earlier implementation dates for new buildings

Smaller Units: January 2026

Larger Units and Pool Heaters: January 2028

High Temperature Units: January 2029

Zero-emission Units are Commercially Available

Incentive programs have installed ~1,000 commercial heat pump water heaters in existing buildings in the region

- TECH Clean California (state-funded)
- Willdan Energy Solutions (funded by Southern California Edison)

Implementation Schedule for Existing Buildings

Longer implementation dates for existing buildings

Smaller Units:
Begins 2029 (15-year implementation)

Larger Units and Pool Heaters:
Begins 2031 (25-year implementation)

High Temperature Units:
January 2033 (25-year implementation)

Additional Compliance Options

Additional time/considerations are provided for situations where:

✓ Utility needs time to complete upgrades

✓ Facilities have five or more units required to be replaced in two consecutive years

✓ Emergency replacement requires electrical upgrade

✓ Mobile home is replacing instantaneous water heater

✓ Unit is low-use or low-emitting

✓ Small businesses are replacing units

✓ Property under lease is relying on landlord for electrical upgrade

✓ Construction is required to expand installation space or relocate unit

Considerations for Small Businesses

- ✓ Allow units to transition to zero-emission at natural replacement, regardless of unit age
- ✓ Several alternative compliance options allow for additional implementation time
 - ✓ Utility upgrades
 - ✓ Construction or relocation of a unit
 - ✓ Properties under lease
- ✓ Low-use units allowed to continue to operate
- ✓ Numerous incentive programs available including upcoming South Coast AQMD program

Establishing future
effective zero-
emission limits sends
strong market signal
to manufacturers
and encourages
manufacturers to
expand product
offerings

Technology Check-in Ensures Market Readiness

Technology check-in and report to Stationary Source Committee by June 1, 2027

- Latest utility and equipment costs
- Updated future forecasted costs
- Check in with manufacturers on technology progress
- Product availability for various applications
- Consider input from future site visits
- Challenges and successes

Future Outreach May Focus On:

Site Visits

Continue to conduct site visits to inform future technology check-in

Outreach

Continue outreach to local businesses and trade groups as deadlines approach, including information on rebate programs

Technology Demonstration

Seek to fund a technology demonstration project focused on high temperature units prior to compliance dates

CEQA and Socioeconomic Impacts

California Environmental Quality Act (CEQA)

- Relies on the CEQA analysis previously conducted for the 2022 AQMP which adequately describes the activities and impacts

Cost Analysis for 2026 to 2057

- Total average annual cost – \$49 to \$97 million (depending on assumptions)
- Average annual job impact – 1,000 jobs foregone (less job growth forecasted)

Cost of Implementation

~5.6 tons of
NO_x reduced
per day

Overall rule implementation is cost-effective

Costs are mitigated:

- Transition at end of unit age
- Lifetime fuel switching cost savings
- Long compliance schedule
- Alternative compliance options

Substantial funds available from federal, state, and local programs

Staff Recommendations

Adopt the Resolution:

Determining that Proposed Amended Rule 1146.2 is a later activity within scope of the Final Program Environmental Impact Report for the 2022 AQMP such that no new environmental document will be required; and

Amending Rule 1146.2 – Emissions of Oxides of Nitrogen from Large Water Heaters, Small Boilers and Process Heaters

BOARD MEETING DATE: June 7, 2024

AGENDA NO. 27

PROPOSAL: Determine That South Coast Air Basin Attainment Plan for 2012 Annual PM_{2.5} Standard Does Not Require a New Environmental Document; and Adopt South Coast Air Basin Attainment Plan for 2012 Annual PM_{2.5} Standard

SYNOPSIS: The South Coast Air Basin is in “serious” nonattainment for the 2012 annual PM_{2.5} National Ambient Air Quality Standard. A plan to attain this standard was originally submitted to U.S. EPA in 2017 but U.S. EPA delayed acting on the plan. In the meantime, near-road air quality monitoring data became eligible for inclusion in State Implementation Plan (SIP) attainment demonstrations, and the plan was withdrawn in 2023 to account for this new data and to satisfy other SIP requirements. A Draft PM 2.5 Plan was developed that demonstrates attainment of the 2012 annual PM_{2.5} standard by 2030 in the South Coast Air Basin. This plan also includes limited additional controls for PM_{2.5} and its precursors to satisfy Clean Air Act Section 188(e) requirements.

COMMITTEE: Mobile Source, October 20, 2023 and March 15, 2024, Reviewed

RECOMMENDED ACTION:

Adopt the attached Resolution:

1. Determining that the Draft South Coast Air Basin Attainment Plan for the 2012 Annual PM_{2.5} Standard (Draft PM_{2.5} Plan) is a later activity within the scope of the Final Program Environmental Impact Report (EIR) for the 2022 AQMP and the Final Program EIR for the 2016 AQMP such that no new environmental document will be required; and
2. Adopting the Draft South Coast Air Basin Attainment Plan for the 2012 Annual PM_{2.5} Standard and directing staff to forward the Draft PM_{2.5} Plan to CARB for approval and submission to U.S. EPA for inclusion in the SIP.

Wayne Nastri
Executive Officer

Background

The South Coast Air Basin (Basin) has some of the highest levels of PM_{2.5} in the nation. PM_{2.5} is either directly emitted into the atmosphere (primary particles) or formed in the atmosphere through chemical reactions (secondary particles). Primary PM_{2.5} includes road dust, diesel soot, combustion products, and other sources of fine particles. Secondary PM_{2.5} is formed from reactions with SO_x, NO_x, VOCs, and ammonia in the atmosphere.

Effective April 15, 2015, U.S. EPA designated the Basin as a “moderate” nonattainment area for the 2012 annual PM_{2.5} NAAQS with an attainment date of December 31, 2021. The 2016 AQMP concluded that attainment by 2021 was impractical and requested reclassification of the Basin to “serious” nonattainment as allowed by the Clean Air Act (CAA), which has an attainment date of December 31, 2025. Accordingly, South Coast AQMD included a serious area attainment plan in the 2016 AQMP that demonstrated attainment by 2025.

The 2016 AQMP was adopted by the Board on March 3, 2017, and staff submitted the 2016 AQMP to CARB and U.S. EPA for approval on April 27, 2017. Despite a requirement in the CAA that U.S. EPA must act on a SIP submittal within 18 months of receipt, U.S. EPA did not act on the portion of the 2016 AQMP that addresses the requirements for the 2012 PM_{2.5} NAAQS “serious” nonattainment area for several years. On December 9, 2020, U.S. EPA approved South Coast AQMD’s request to reclassify the Basin from moderate to serious nonattainment for the 2012 annual PM_{2.5} NAAQS.

Since the adoption of the 2016 AQMP, two near-road monitors established along the Interstate 710 (I-710) in Long Beach and the California State Route 60 (CA-60) in Ontario accumulated sufficient data to be considered in SIP attainment demonstrations. Based on 2020–2022 monitoring data, the CA-60 near-road monitoring site had the highest PM_{2.5} level in the Basin at 13.7 µg/m³. Subsequently, U.S. EPA indicated that it could not approve the submitted “serious” area plan which did not address attainment of a site showing the highest level of PM_{2.5} in the Basin.

In January 2023, U.S. EPA was legally challenged over its failure to act timely on the PM_{2.5} plan addressing “serious” nonattainment area requirements for the 2012 NAAQS. On March 29, 2023, given the concerns regarding approvability of the plan for the 2012 annual PM_{2.5} NAAQS, South Coast AQMD withdrew the plan via CARB. As a consequence of withdrawal, U.S. EPA issued failures to submit the required SIP elements, which triggered sanction clocks. South Coast AQMD is required to develop a new plan to address SIP requirements for the 2012 annual PM_{2.5} NAAQS and submit to U.S. EPA no later than December 26, 2024 to avoid sanctions.

Proposal

A Draft PM2.5 Plan has been developed to demonstrate how the Basin will attain the 2012 annual PM2.5 NAAQS and address federal CAA SIP requirements. Air quality modeling demonstrates that attainment by December 31, 2025 would be impractical and the Draft PM2.5 Plan therefore requests a five-year extension of the attainment date to December 31, 2030, as allowed by CAA Section 188(e). The Basin is expected to attain the 2012 annual PM2.5 NAAQS by 2030 by continuing to implement the 2022 AQMP NOx strategy, along with limited additional controls on direct PM2.5 and precursor emissions to satisfy U.S. EPA's stringency requirements. Overall, NOx and PM2.5 emissions are expected to decline by 54 and 6 percent, respectively, between 2018 and 2030, which will be sufficient to lead the Basin into attainment of the 2012 annual PM2.5 NAAQS.

The Draft PM2.5 Plan seeks to comply with all CAA requirements, including the requirements under CAA Section 188(e) for a five-year extension of the attainment date. Among those is a requirement to demonstrate the implementation of Most Stringent Measures (MSM), which is defined as the maximum degree of emission reduction that has been required or achieved from a source or source category in any other attainment plans or in practice in any other states. In addition to the 2022 AQMP NOx control measures, the Draft PM2.5 Plan includes South Coast AQMD's commitment to adopt and implement four control measures to satisfy MSM requirements. These measures include lowering the applicability thresholds for dairies and poultry farms to acquire permits and to reduce ammonia emissions (BCM-08), requiring composting of chipped and ground greenwaste prior to land application (BCM-10), lowering the applicability threshold for chain-driven charbroilers to install and operate catalytic oxidizer (BCM-12), and removing the low-income exemption in residential wood-burning curtailment program (BCM-18).

Public Process

Staff convened the AQMP and Scientific, Technical, and Modeling Peer Review (STMPR) Advisory Groups during development of the Draft PM2.5 Plan. The Draft PM2.5 Plan was released on March 22, 2024 and four regional public hearings were held on April 23, 24, and 25, and May 1, 2024. Overall, two written comments were received on the Draft PM2.5 Plan and responses are included in Chapter 8 of the PM2.5 Plan.

Resource Impacts

The PM2.5 Plan will have nominal impacts on South Coast AQMD resources. This is because the NOx control strategy developed for the 2022 AQMP will be sufficient to lead the Basin into attainment of the 2012 annual PM2.5 NAAQS by 2030.

California Environmental Quality Act (CEQA)

Pursuant to the CEQA, South Coast AQMD, as lead agency, reviewed the proposed project (PM2.5 Plan) and determined that: 1) the PM2.5 Plan implements a selected

suite of control measures that were previously adopted in the 2022 AQMP and the 2016 AQMP; 2) the Final Program Environmental Impact Report (EIR) for the 2022 AQMP and the Final Program EIR for the 2016 AQMP evaluated the control measures which are being relied upon for the PM2.5 Plan, and analyzed their potential environmental impacts; 3) no subsequent EIR would be required per CEQA Guidelines Section 15168 (c)(2) because there are no new or modified physical changes that would result from implementing the PM2.5 Plan which were not previously analyzed in the Final Program EIR for the 2022 AQMP and the Final Program EIR for the 2016 AQMP; and 4) the Final Program EIR for the 2022 AQMP and the Final Program EIR for the 2016 AQMP can be relied on for CEQA compliance. Thus, the PM2.5 Plan is a later activity within the scope of the program approved earlier in the 2022 AQMP and the 2016 AQMP per CEQA Guidelines 15168 (c), and the Final Program EIR for the 2022 AQMP and the Final Program EIR for the 2016 AQMP adequately describe and analyze the activities associated with implementing the PM2.5 Plan for the purposes of CEQA such that no new environmental document will be required. The analysis supporting this conclusion can be found in Appendix VIII of the PM2.5 Plan.

Socioeconomic Impact Assessment

The control measures upon which the Draft PM2.5 Plan relies were previously adopted in either the 2022 AQMP or the 2016 AQMP and there is no material change to the estimated costs previously analyzed in the respective Socioeconomic Impact Assessments. However, the health benefits for attainment year 2030 were not previously quantified. The analysis of implementing the Draft PM2.5 Plan control strategies in the 2030 attainment year indicates an additional reduction in risks from premature deaths and numerous other health effects associated with air pollution among residents in the South Coast Air Basin. The details of the Socioeconomic Impact Assessment can be found in Appendix VII of the PM2.5 Plan.

AQMP and Legal Mandates

The PM2.5 Plan is consistent with the federal CAA and the U.S. EPA's guidelines and is required as part of the SIP revision to address the federal CAA requirements for "serious" nonattainment areas.

ATTACHMENT A

RESOLUTION NO. 24-_____

A Resolution of the South Coast Air Quality Management District (South Coast AQMD) Governing Board determining that the South Coast Air Basin Attainment Plan for the 2012 Annual PM2.5 Standard (PM2.5 Plan) qualifies as a later activity within the scope of the program approved earlier for the 2022 Air Quality Management Plan (AQMP) and the 2016 AQMP per California Environmental Quality Act (CEQA) Guidelines Section 15168 (c), and the Final Program Environmental Impact Report (EIR) for the 2022 AQMP adequately describes the activity for the purposes of CEQA such that no new environmental document is required.

A Resolution of the South Coast AQMD approving the PM2.5 Plan and directing staff to forward South Coast AQMD's PM2.5 Plan to the California Air Resources Board (CARB) for approval and submission to the United States Environmental Protection Agency (U.S. EPA) for inclusion in the State Implementation Plan (SIP).

WHEREAS, the South Coast AQMD Governing Board finds and determines that the PM2.5 Plan is considered a "project" as defined by the California Environmental Quality Act (CEQA); and

WHEREAS, the South Coast AQMD Governing Board finds and determines that: 1) the PM2.5 Plan implements a selected suite of control measures that were previously adopted in the 2022 AQMP and the 2016 AQMP; 2) the Final Program EIR for the 2022 AQMP and the Final Program EIR for the 2016 AQMP evaluated the control measures which are being relied upon for the PM2.5 Plan, and analyzed their potential environmental impacts; 3) no subsequent EIR would be required per CEQA Guidelines Section 15168 (c)(2) because there are no new or modified physical changes that would result from implementing the PM2.5 Plan which were not previously analyzed in the Final Program EIR for the 2022 AQMP and the Final Program EIR for the 2016 AQMP; and 4) the Final Program EIR for the 2022 AQMP and the Final Program EIR for the 2016 AQMP can be relied on for CEQA compliance; and

WHEREAS, the South Coast AQMD Governing Board finds and determines that the PM2.5 Plan is a later activity within the scope of the program approved earlier in the 2022 AQMP and the 2016 AQMP per CEQA Guidelines Section 15168 (c)(2), and the Final Program EIR for the 2022 AQMP and the Final Program EIR for the 2016 AQMP adequately describe the activity associated with implementing the PM2.5 Plan for the purposes of CEQA such that no new environmental document will be required; and

WHEREAS, the South Coast AQMD Governing Board finds and determines that based on substantial evidence in the record and in accordance with the noticing requirements in CEQA Guidelines Section 15168 (e), the PM2.5 Plan qualifies as a later activity within the scope of the program approved earlier for the 2022 AQMP and 2016 AQMP, and the Final Program EIR for the 2022 AQMP and the Final Program EIR for the 2016 AQMP adequately describe the activity for the purposes of CEQA; and

WHEREAS, the South Coast Air Basin is a “serious” nonattainment area for the 2012 annual PM2.5 standard with an attainment date of December 31, 2025; and

WHEREAS, a plan to attain the 2012 annual PM2.5 standard by 2025 was submitted to the U.S. EPA in 2017. However, that plan was withdrawn in 2023 due to U.S. EPA’s delay in considering the plan and subsequent availability of new near-road air quality monitoring data, triggering the need to develop a revised plan; and

WHEREAS, the PM2.5 Plan seeks a five-year extension of the attainment date to 2030, as allowed by Clean Air Act Section 188(e), to address challenges associated with near-road air quality monitors; and

WHEREAS, the South Coast Air Basin is expected to attain the 2012 annual PM2.5 standard in 2030 with the implementation of the 2022 AQMP strategy and limited additional controls to reduce PM2.5 and its precursor emissions as identified in this PM2.5 Plan; and

WHEREAS, the PM2.5 Plan includes an expeditious adoption and implementation schedule of control measures in a cost-effective, feasible, and targeted fashion; and

WHEREAS, the PM2.5 Plan addresses applicable federal CAA requirements, including the implementation of Best Available Control Measures (BACM), Most Stringent Measures (MSM), a Reasonable Further Progress (RFP) demonstration, a comprehensive emissions inventory, a control strategy, an attainment demonstration, contingency measures, quantitative milestones, a transportation conformity budget, and other “serious” nonattainment area SIP requirements; and

WHEREAS, the South Coast AQMD held three AQMP Advisory Group meetings and two Scientific, Technical, and Modeling Peer Review Advisory Group meetings; and

WHEREAS, the Draft PM2.5 Plan was released for public review and comment on March 22, 2024 with a 46-day comment period from March 22, 2024 to May 7, 2024; and

WHEREAS, four regional public hearings were held on April 23, 24, 25, and May 1, 2024 to discuss the Draft PM2.5 Plan. Notice was given of these hearings pursuant to the requirements under the Health and Safety Code Section 40466; and

WHEREAS, the Draft Socioeconomic Impact Assessment for the PM2.5 Plan, provided in Appendix VII of the PM2.5 Plan, was prepared and released for public review and comment on May 2, 2024; and

WHEREAS, the South Coast AQMD Governing Board has considered the Socioeconomic Impact Assessment for the PM2.5 Plan and has made a good faith effort to minimize any adverse impacts; and

WHEREAS, the public hearing has been properly noticed in accordance with all provisions of Health and Safety Code Section 40466 and Code of Federal Regulations Title 40, Part 51, Section 51.102; and

WHEREAS, the South Coast AQMD Governing Board has held a public hearing in accordance with all provisions of law; and

WHEREAS, the South Coast AQMD specifies the Planning and Rules Manager of the PM2.5 Plan as the custodian of the documents or other materials which constitute the record of proceedings upon which the adoption of the PM2.5 Plan is based, which are located at the South Coast AQMD, 21865 Copley Drive, Diamond Bar, California; and

NOW, THEREFORE BE IT RESOLVED, that the South Coast AQMD Governing Board does hereby determine, pursuant to the authority granted by law, that the PM2.5 Plan qualifies as a later activity within the scope of the program approved earlier for the 2022 AQMP and the 2016 AQMP per CEQA Guidelines 15168 (c), and the Final Program EIR for the 2022 AQMP and the Final Program EIR for the 2016 AQMP adequately describe the activity for the purposes of CEQA such that no new environmental document will be required. This information was presented to the South Coast AQMD Governing Board, whose members exercised their independent judgement and reviewed, considered, and approved the information therein prior to acting on the proposed project; and

BE IT FURTHER RESOLVED, that the South Coast AQMD will develop, adopt, submit, and implement applicable control measures in Tables 4-2 and 4-3 of Chapter 4 in the PM2.5 Plan as expeditiously as possible in order to meet or exceed the commitments identified in Table 4-12 of the PM2.5 Plan to attain the 2012 annual PM2.5 standard, and to substitute any other measures as necessary to make up any emission reduction shortfall; and

BE IT FURTHER RESOLVED, that the proposed commitment for emission reductions is for total aggregate emissions reductions that may be achieved through the measures identified in the PM2.5 Plan, alternative measures, incentive programs, and actual emission decreases; and

BE IT FURTHER RESOLVED, that the South Coast AQMD Governing Board, whose members reviewed, considered and approved the information contained in the documents listed herein, adopts the PM2.5 Plan dated June 7, 2024 consisting of the document entitled South Coast Air Basin Attainment Plan for the 2012 Annual PM2.5 Standard as amended by the final changes, if applicable, set forth by the South Coast AQMD Governing Board; and

BE IT FURTHER RESOLVED, that the South Coast AQMD Governing Board directs the Executive Officer to work with CARB and the U.S. EPA and take appropriate action to resolve any completeness or approvability issues that may arise regarding the SIP submission; and

BE IT FURTHER RESOLVED, that the Executive Officer is hereby directed to forward a copy of this Resolution and the PM2.5 Plan to CARB for approval and subsequent submittal to the U.S. EPA for inclusion in the SIP.

EXECUTIVE SUMMARY

- Despite great strides in cleaning the air over the past several decades, the Los Angeles area still has among the highest levels of fine particulate matter (PM2.5) pollution in the nation.
- The South Coast Air Basin fails to meet the 2012 annual PM2.5 national ambient air quality standard and is classified as a “serious” nonattainment area.
- South Coast AQMD submitted a plan to attain the 2012 annual PM2.5 standard by 2025 in 2017; however, the U.S. EPA failed to take timely action on that plan. Due to unforeseen challenges, that plan would no longer provide a path to attaining the standard.
- South Coast AQMD developed a new plan to meet the 2012 annual PM2.5 standard. To address the unforeseen challenges, this plan seeks an extension of the attainment date to 2030 as allowed by the Clean Air Act.
- The new plan requires accelerated implementation of control measures from the 2022 AQMP as well as limited additional measures to reduce ammonia and direct PM2.5 emissions.
- With the emission reductions expected from the strategy listed above, the South Coast Air Basin is expected to meet the 2012 annual PM2.5 standard by 2030.

Overview

The 17 million residents of the greater Los Angeles area have suffered from some of the worst air quality in the nation. While air quality has improved greatly over the past decade, more needs to be done. The region has the worst levels of ground-level ozone (smog) and among the highest levels of fine particulate matter (PM2.5). PM2.5 is an air pollutant that is either directly emitted into the atmosphere (primary particles) or formed in the atmosphere through chemical reactions (secondary particles). Primary PM2.5 includes road dust, diesel soot, combustion products, and other sources of fine particles. Secondary PM2.5 products, such as sulfates, nitrates, and complex organic compounds, are formed from reactions with oxides of sulfur (SOx), oxides of nitrogen (NOx), volatile organic compounds (VOCs), and ammonia.

The PM2.5 air pollution levels in the region exceed both National and California Ambient Air Quality Standards. High levels of air pollution cause respiratory and cardiovascular disease, exacerbate asthma, and can lead to premature death. We also know that our Environmental Justice (EJ) communities experience the brunt of adverse health effects from air pollution. Approximately 42 percent of the South Coast Air Basin (Basin) residents live in EJ communities.

The United States Environmental Protection Agency (U.S. EPA) requires areas that do not meet a National Ambient Air Quality Standard (NAAQS or standard) to develop and implement strategies to reduce emissions so that healthy levels of air quality can be achieved in a timely manner. The strategy, along with other supporting elements, must be submitted to U.S. EPA for its review and approval into the State Implementation Plan (SIP). Regions must develop SIPs to attain NAAQS by specific dates or face the possibility of sanctions by the federal government and other consequences under the Clean Air Act (CAA). This can result in increased permitting fees, stricter restrictions for permitting new projects, and the loss of federal highway funds.

This document addresses the planning requirements for the 2012 annual PM2.5 NAAQS. The Basin fails to meet ~~this NAAQS for the 2012 annual PM2.5~~ standard and is currently classified as a “serious” nonattainment area. As such, the South Coast AQMD is required by the Clean Air Act to develop a plan to meet the NAAQS. This document is the plan that provides the strategy and the underlying technical analysis for how the Basin will meet the 2012 annual PM2.5 NAAQS as expeditiously as practicable, but no later than December 31, 2030. This Plan does not address the Coachella Valley as that area already attains the 2012 annual PM2.5 NAAQS.

Challenges and Need for a New PM_{2.5} Plan

Effective April 15, 2015, the U.S. EPA designated the Basin as a “moderate” nonattainment area for the 2012 annual PM_{2.5} NAAQS.¹ The 2016 Air Quality Management Plan (AQMP) contained the original plan to meet the 2012 annual PM_{2.5} NAAQS. In that plan, staff concluded that attainment by the “moderate” area deadline of December 31, 2021 was not achievable. As provided for under the Clean Air Act, staff requested that the U.S. EPA reclassify the Basin to “serious” nonattainment, which provided for additional time to attain the standard. Accordingly, a “serious” area attainment plan, demonstrating attainment by December 31, 2025, was also included in the 2016 AQMP.

Despite the 2016 AQMP submittal, U.S. EPA did not act on the PM_{2.5} “serious” area plan for several years. On December 9, 2020, U.S. EPA reclassified the Basin from “moderate” to “serious” nonattainment for the 2012 annual PM_{2.5} NAAQS with an attainment deadline by December 31, 2025.² U.S. EPA simultaneously raised concerns regarding data from near-road monitors which were established in 2015. These monitors are located along the Interstate 710 (I-710) in Long Beach and the California State Route 60 (CA-60) in Ontario. At the time of 2016 AQMP adoption, neither of these monitors had collected enough data to be considered in plans. By January 1, 2020, however, these monitors had accumulated sufficient data to be considered in SIP attainment demonstrations. Based on 2020–2022 monitoring data, the CA-60 near-road monitoring site had the highest PM_{2.5} level in the Basin at 13.7 µg/m³. U.S. EPA indicated that it could not approve the “serious” area plan included in the 2016 AQMP since, at the time the reclassification request was approved, the near-road monitors were now eligible to be considered in attainment demonstrations. U.S. EPA subsequently requested a supplemental attainment demonstration for the near-road monitors.

On January 12, 2023, U.S. EPA was sued over its failure to take timely action on the “serious” area plan in the 2016 AQMP. To avoid potential disapproval of the plan by U.S. EPA, which would have triggered sanction clocks, South Coast AQMD withdrew the “serious” area plan. As a consequence of withdrawal, South Coast AQMD is required to develop a new plan to address attainment of the 2012 annual PM_{2.5} NAAQS.

While the 2016 AQMP had predicted attainment of the 2012 annual PM_{2.5} NAAQS by 2025, this PM_{2.5} Plan requests an attainment date extension to December 31, 2030 as allowed under CAA Section 188(e). There are multiple factors contributing to the extension of the attainment date. The addition of the near-road monitors, which were not considered in the 2016 AQMP, is one of the primary reasons for the longer timeframe needed for attainment. In addition, due to a lack of action at the federal level, sources such as interstate trucks, ships, locomotives, and aircraft have not been controlled sufficiently, which has resulted

¹ Air Quality Designations for the 2012 Primary Annual Fine Particle (PM_{2.5}) National Ambient Air Quality Standards (NAAQS), 80 Fed. Reg. 2206 (Jan. 15, 2015)

² Approval and Promulgation of Implementation Plans; Designation of Areas for Air Quality Planning Purposes; California; South Coast Moderate Area Plan and Reclassification as Serious Nonattainment for the 2012 PM_{2.5} NAAQS, 85 Fed. Reg. 71264 (Nov. 9, 2020)

in emission reduction shortfalls for attainment of ozone standards. Other unforeseen challenges that have complicated attainment include unfavorable meteorology, wildfires, and increases in emissions in the goods movement sector during the COVID-19 pandemic.

Control Measures and Attainment Strategy

U.S. EPA requires PM2.5 plans to address directly-emitted PM2.5 and the gases that form PM2.5 in the atmosphere. These gases are known as precursors, and they include SOx, NOx, VOCs, and ammonia. While the main sources of NOx are on-road and off-road mobile sources, direct PM2.5 emissions are driven by stationary area sources, such as cooking and resuspended particles from paved roads. Ammonia emissions are driven by both area and mobile sources. Control measures for VOCs and SOx are not included in the attainment strategy as these precursors have an insignificant contribution to PM2.5 in the Basin.

The reductions needed to meet the 2012 annual PM2.5 NAAQS will come from three categories.

- 1) **Already adopted rules and programs.** Rules and programs that have already been adopted by the South Coast AQMD will continue to bring emission reductions of PM2.5 and its precursors. These reductions are already reflected in the baseline (i.e., Business-As-Usual) emissions. Under baseline conditions, NOx and direct PM2.5 emissions are expected to decline by 45 percent and 4 percent from 2018 to 2030, respectively.
- 2) **Actions from the 2022 AQMP.** The NOx strategy committed in the 2022 AQMP to attain the 2015 8-hour ozone NAAQS by 2037 is expected to reduce both NOx and direct PM2.5 emissions by 2030. Among the control measures included in the 2022 AQMP, those that can be implemented by 2030 were identified and included in this Plan. Both NOx emission reductions and concurrent PM2.5 reductions from 2022 AQMP NOx control measures were quantified in this PM2.5 Plan.
- 3) **Limited additional reductions of ammonia and direct PM2.5.** These additional reductions will be pursued to satisfy U.S. EPA's stringency requirements. This PM2.5 Plan is required to satisfy U.S. EPA's requirements including Best Available Control Measures (BACM) and Most Stringent Measures (MSM). Demonstrating BACM and MSM is independent of attainment and therefore some control measures, which are surplus to the attainment strategy, are included. For details on the BACM and MSM requirements and analysis, refer to Appendix III.

South Coast AQMD proposes a total of 38 control measures for the PM2.5 Plan. Out of the 38 proposed control measures, 23 measures target reductions from stationary sources and the remaining 15 measures target reductions from mobile sources. The stationary source measures are grouped into the following categories: NOx measures, direct PM2.5 measures, ammonia measures, co-benefits from energy and climate change programs, and other measures. Meanwhile, the mobile source measures are grouped into the following categories: emission growth management measures, facility-based mobile source measures, on-road and off-road measures, incentive-based measures, and other measures. Overall, emissions of

NOx and PM2.5 will reduce by 207.7 tons per day and 3.4 tons per day, respectively, between 2018 and 2030.

Attainment Demonstration

Air quality modeling is used to demonstrate future attainment of the PM2.5 standard and is an integral part of the planning process. Modeling shows the connection between emission reductions and a path to attainment. It reflects updated emissions estimates, new technical information, enhanced air quality modeling techniques, updated attainment demonstration methodology, and the control strategy.

The modeling platform consists of a suite of modeling tools that calculate air pollutant emissions, meteorological conditions that drive the transport of pollutants, and chemical transformation of pollutants to predict the concentrations of PM2.5 and its precursors. The modeling setup is an upgrade from the modeling platform used in the 2022 AQMP and incorporates new versions of the Weather Research Forecast (WRF) meteorological model and the Community Multiscale Air Quality (CMAQ) model. Emissions modeling incorporates detailed information from satellite observations, vehicle traffic sensor data, and communication platforms for aircraft and ocean-going vessels, to refine emissions spatial and temporal distribution.

For the first time in a South Coast Air Basin PM2.5 plan, the design site for the annual PM2.5 standard is a near-road monitor. That site is the near-road monitor that is located by the CA-60 freeway in Ontario. Modeling the air quality in this site presents challenges to regional air quality models commonly used in attainment demonstrations. The U.S. EPA modeling guidance for attainment demonstrations³ recognizes the limitations of regional models to represent the steep gradients in PM2.5 around near-road sites and acknowledges that demonstrating attainment at near-road sites may require different treatment compared to other monitors. This PM2.5 plan employs a hybrid approach that combines traditional regional modeling with dispersion modeling around the near-road site. The hybrid modeling helps characterize the contribution of near-road sources to measured PM2.5 at the near-road monitor to better quantify the benefits of emission controls on on-road sources. Other than the near-road monitor at Ontario CA-60, the traditional regional modeling approach was employed to demonstrate attainment at all stations in the Basin.

With the proposed control measures and emissions reductions, the attainment strategy in this Plan will result in meeting the 2012 annual PM2.5 standard by 2030 at all the stations in the Basin.

Health Benefits

A Socioeconomic Impact Assessment, which includes quantification of public health benefits, is being prepared and will be released for public review at least 30 days prior to the Public Hearing.

Collaboration, Public Process, and Outreach

The development of the PM_{2.5} Plan has been a regional, multi-agency effort that includes South Coast AQMD, CARB, the Southern California Association of Governments, and the U.S. EPA. The PM_{2.5} Plan also incorporates collaborative efforts by a wide range of stakeholders such as businesses, environmental and health organizations, community groups, and academia. As shown in Figure ES-1, development of the PM_{2.5} Plan involved numerous types of public meetings to promote collaboration and public participation. Meeting materials for the regional public hearings ~~will be~~were translated to Spanish and ~~will all hearings featured~~were provided with—live Spanish translation. Agendas and presentations for each meeting will be forthcoming.

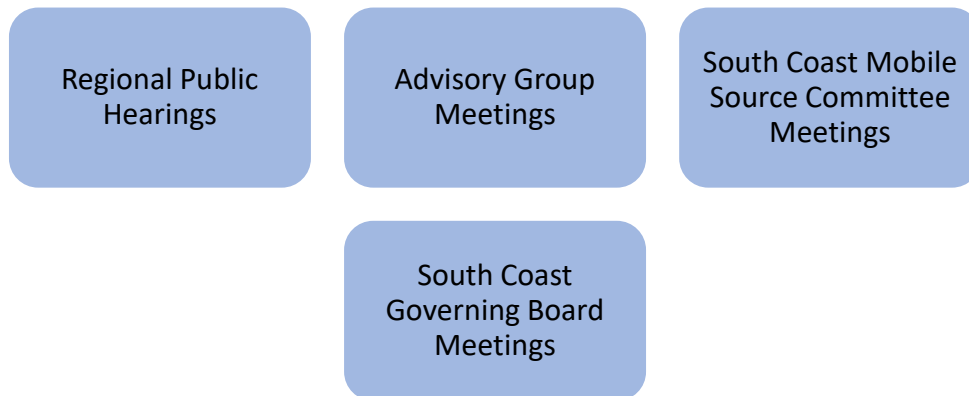

FIGURE ES-1
VENUES ACCOMMODATING STAKEHOLDER PARTICIPATION

Implications of a New PM_{2.5} Standard for the Basin

U.S. EPA recently revised the annual PM_{2.5} standard from its current level of 12 µg/m³ to 9.0 µg/m³.⁴ The new standard is the result of an extensive scientific review conducted by U.S. EPA's Clean Air Scientific

⁴ Reconsideration of the National Ambient Air Quality Standards for Particulate Matter, 89 Fed. Reg. 16202 (Mar. 6, 2024)

Advisory Committee (CASAC), which found that the 12 $\mu\text{g}/\text{m}^3$ standard does not sufficiently protect public health.

This PM_{2.5} Plan, together with the 2022 AQMP, serves as a steppingstone for attaining the 2024 PM_{2.5} NAAQS. However, even after implementing the control strategy of this Plan, air quality modeling predicts that the 2030 design value will be 11.7 $\mu\text{g}/\text{m}^3$, significantly higher than the new 9.0 $\mu\text{g}/\text{m}^3$ standard. Preliminary results suggest that even implementation of the 2022 AQMP strategy, which targets attainment of the 2015 8-hour ozone NAAQS by 2037, will be insufficient to lower the design value to 9.0 $\mu\text{g}/\text{m}^3$. Substantial emission reductions especially of direct PM_{2.5} will therefore be required to meet the new standard. South Coast AQMD commits to develop the optimal attainment strategy that considers stakeholder feedback while ensuring expeditious attainment of the 2024 PM_{2.5} standard.

CHAPTER 1

Introduction

- PM2.5 levels have improved dramatically in the South Coast Air Basin (Basin) over the past several decades, yet the region still experiences among the highest PM2.5 levels in the nation, leading to significant health issues.
- The Basin is in “serious” nonattainment of the 2012 annual PM2.5 standard and the Clean Air Act requires South Coast AQMD to develop and implement an emission reduction strategy to meet the standard.
- This document is the plan to meet the 2012 annual PM2.5 standard in the Basin by December 31, 2030.
- The emission reductions to be achieved through implementing this plan will assist the Basin in meeting the 2024 annual PM2.5 standard.

Purpose

The greater Los Angeles area experiences some of the worst air pollution in the nation. While tremendous progress has been made in reducing levels of air pollution over that past several decades, the region still has the highest levels of ozone, and among the highest levels of fine particulate matter (PM_{2.5}) in the country. These air pollutants cause substantial health impacts, including respiratory and cardiovascular disease, worsening asthma symptoms, and premature death.

The federal Clean Air Act (CAA or Act) requires areas that do not meet the health-based National Ambient Air Quality Standards (NAAQS or standards) to develop and implement an emission reduction strategy to attain healthy levels of air quality in a timely manner. The South Coast Air Basin (Basin) fails to meet the 2012 annual PM_{2.5} NAAQS and is currently classified as a “serious” nonattainment area for that standard. The South Coast Air Basin Attainment Plan for the 2012 Annual PM_{2.5} Standard (PM_{2.5} Plan or Plan) provides the strategy and the underlying technical analysis for how the region will meet the 2012 annual PM_{2.5} NAAQS in the Basin as expeditiously as practicable, but no later than December 31, 2030. This Plan does not address the Coachella Valley as that area already meets the 2012 annual PM_{2.5} NAAQS. It also does not address attainment of other NAAQS as those are addressed in the 2016 and 2022 Air Quality Management Plans (AQMPs).^{1,2}

Federal 2012 Annual PM_{2.5} Standard

On December 14, 2012, the U.S. EPA strengthened the primary annual NAAQS for PM_{2.5} to 12 micrograms per cubic meter (µg/m³).³ Under the CAA, there are two tiers of nonattainment for areas that fail to meet PM_{2.5} standards; “moderate” and “serious.” Nonattainment areas are classified by the U.S. EPA into one of these two tiers based on the levels of PM_{2.5} in the region. Effective April 15, 2015, the U.S. EPA designated the South Coast Air Basin (Basin) as a “moderate” nonattainment area for the 2012 annual PM_{2.5} NAAQS.⁴ Pursuant to Clean Air Act (CAA) Section 189(a)(2)(B), “moderate” nonattainment areas must submit a plan showing how the region will meet the standard by the date required by the CAA, no later than 18 months from the date of designation. “Moderate” nonattainment areas are required to meet the 2012 annual PM_{2.5} standard as expeditiously as practicable, but no later than the end of the sixth calendar year after the designation (i.e., December 31, 2021) and “serious” nonattainment areas are required to attain the standard as expeditiously as practicable, but no later than the end of the tenth calendar year after the designation (i.e., December 31, 2025). Under CAA Section 188(e), “serious”

nonattainment areas may request an attainment date extension to no later than the end of the fifteenth calendar year after the designation (i.e., December 31, 2030).

California Annual PM_{2.5} Standard

The California Clean Air Act (CCAA),⁵ enacted in 1988, provides a framework for air quality planning and established a legal mandate for CARB to achieve health-based state air quality standards for ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide at the earliest practicable date. Although not required by the CCAA, state standards for particulate matter are contained in Title 17 of the California Code of Regulations (CCR).⁶ In June 2002, CARB promulgated the state annual average PM_{2.5} standard of 12 µg/m³ for which the Basin is designated nonattainment. The CCAA specifies multiple requirements for ozone plans, such as requiring plans to be reviewed every three years, demonstrating plan effectiveness, implementing all feasible measures, reducing population exposure, and ranking control measures by cost-effectiveness.⁷ However, these CCAA requirements do not directly apply to PM_{2.5} plans and no requirements were specified for PM_{2.5}.

2016 AQMP

The South Coast AQMD developed the 2016 AQMP as the comprehensive blueprint for how the region will attain five NAAQS – three ozone standards (1979 1-hour, 1997 8-hour and 2008 8-hour), the 2006 24-hour PM_{2.5} standard and the 2012 annual PM_{2.5} standard. The 2016 AQMP concluded that attainment by the “moderate” area deadline of December 31, 2021, was impractical and requested reclassification of the Basin to “serious” nonattainment for the 2012 annual PM_{2.5} standard as provided in the CAA. Accordingly, South Coast AQMD included a “serious” area attainment plan in the 2016 AQMP that demonstrated attainment by December 31, 2025. The 2016 AQMP was adopted by the South Coast AQMD Governing Board on March 3, 2017, and submitted to U.S. EPA for approval on April 27, 2017, via the California Air Resources Board (CARB).

The CAA requires U.S. EPA to determine the completeness of any State Implementation Plan (SIP) submittal within 6 months of receipt and take final action on the submitted SIP by approving or disapproving, either in full or in part, within 12 months of the date the submittal has been deemed complete.⁸ Despite the SIP being deemed complete by operation of law on October 27, 2017, U.S. EPA did not act on the PM_{2.5} “serious” area plan for several years. On December 9, 2020, U.S. EPA reclassified the Basin from “moderate” to “serious” nonattainment for the 2012 annual PM_{2.5} NAAQS per South Coast

⁸ 42 U.S.C. § 7410(k)(1)–(4)

AQMD's previous request, establishing an attainment deadline of December 31, 2025.⁹ U.S. EPA committed to evaluate and act on the PM_{2.5} "serious" area plan through subsequent rulemakings.

U.S. EPA's Concerns with the Annual PM_{2.5} Plan in the 2016 AQMP

Since the adoption of the 2016 AQMP, new challenges emerged that were not considered in the "serious" area plan. In 2015, two near-road monitors were established in the Basin, along the Interstate 710 (I-710) in Long Beach and the California State Route 60 (CA-60) in Ontario. When the U.S. EPA strengthened the annual PM_{2.5} NAAQS to 12 µg/m³ on December 14, 2012, it added a requirement to monitor near the most heavily trafficked roadways in large urban areas. Particle pollution is expected to be higher along these roadways as a result of direct emissions from cars and heavy-duty diesel trucks and buses. The South Coast AQMD installed the two required PM_{2.5} monitors before January 1, 2015. The locations are I-710, located at Long Beach Blvd. in Los Angeles County near Compton and Long Beach; and CA-Route 60, located west of Vineyard Avenue near Ontario, Mira Loma and Upland. —At the time of 2016 AQMP adoption, these monitors had not collected sufficient data to establish valid design values, which requires three years of valid data. As a result, the data from the near-road monitors were excluded from the attainment demonstration. By January 1, 2020, these monitors had accumulated sufficient data to establish design values, allowing them to be considered in SIP attainment demonstrations.

Based on 2020–2022 monitoring data, the CA-60 near-road monitoring site had the highest PM_{2.5} level in the Basin at 13.7 µg/m³. This is above the 2012 annual standard of 12 µg/m³. U.S. EPA indicated that it could not approve the "serious" area attainment demonstration included in the 2016 AQMP since, at the time the reclassification request was approved, the near-road monitors were eligible to be considered in attainment demonstrations. U.S. EPA subsequently requested a supplemental attainment demonstration that included data from the near-road monitors.

Need for a New PM_{2.5} Plan

On January 12, 2023, the Center for Biological Diversity sued U.S. EPA over its failure to act on the "serious" area plan in the 2016 AQMP by the statutory due date. As U.S. EPA indicated that the 2016 plan was no longer approvable, South Coast AQMD submitted a request via CARB on March 29, 2023, to withdraw the 2016 AQMP "serious" area plan for the 2012 annual PM_{2.5} NAAQS. As a consequence of withdrawal, South Coast AQMD is required to develop a new plan to address attainment of the 2012 annual PM_{2.5} NAAQS.

⁹ Approval and Promulgation of Implementation Plans; Designation of Areas for Air Quality Planning Purposes; California; South Coast Moderate Area Plan and Reclassification as Serious Nonattainment for the 2012 PM_{2.5} NAAQS, 85 Fed. Reg. 71264 (November 9, 2020)

While the 2016 AQMP had predicted attainment of the 2012 annual PM_{2.5} NAAQS by 2025, this PM_{2.5} Plan requests an attainment date extension to December 31, 2030, as allowed under CAA Section 188(e). There are multiple factors contributing to the extension of the attainment date. The addition of the near-road monitors, which were not considered in the 2016 AQMP, is one of the primary reasons for the longer timeframe needed for attainment due to the high levels of PM_{2.5} at those monitors. In addition, the attainment strategy in the 2016 AQMP relied on co-benefits from measures to attain the 1997 8-hour ozone standard by 2023 and the 2008 8-hour ozone standard by 2031. Since the submittal of the 2016 AQMP, South Coast AQMD has implemented control measures and achieved emission reductions reflected in the 2016 AQMP attainment demonstration. However, a transition to low emission technologies did not occur across all sources, primarily due to a lack of action at the federal level to address emissions from aircraft, ships, trains, portions of heavy-duty trucks, and off-road equipment. These heavy-duty mobile sources contribute most of the pollution in the region and are subject to federal regulatory authority with limited ability for local regulation. Additional challenges that were not foreseen at the time of 2016 AQMP adoption include unfavorable meteorology, wildfires, increases in emissions in the goods movement sector during the COVID-19 pandemic, and the addition of the near-road monitors.

This PM_{2.5} Plan reviews the current status of PM_{2.5} air quality from all monitors in the region, develops a new strategy to attain the 2012 annual PM_{2.5} NAAQS as expeditiously as practicable, but no later than December 31, 2030, and satisfies all applicable “serious” area requirements.

Format of This Document

This document is organized into seven chapters, each addressing a specific topic. Each of the chapters is summarized here.

Chapter 1, “Introduction,” includes background on the annual PM_{2.5} standard, 2016 AQMP, U.S. EPA’s concerns with the annual PM_{2.5} plan in the 2016 AQMP, and the need for a new plan to address the standard.

Chapter 2, “Air Quality,” discusses the Basin’s current PM_{2.5} air quality in comparison with federal and State health-based air pollution standards and exceptional events.

Chapter 3, “Emissions Inventory,” summarizes the emissions inventory, estimates current emissions by source, and projects future emissions.

Chapter 4, “Control Strategy,” presents the control strategy, specific control measures for stationary and mobile sources, and implementation schedules to attain the 2012 annual PM_{2.5} standard by the specified attainment date.

Chapter 5, “Attainment Demonstration,” describes the air quality modeling approach used in the PM_{2.5} Plan.

Chapter 6, “Federal Clean Air Act Requirements,” discusses requirements associated with the request to extend the attainment date, the motor vehicle emissions budget, Reasonable Further Progress, quantitative milestones, and contingency measures.

Chapter 7, “Environmental Justice Communities,” describes air quality impacts experienced in environmental justice communities and outlines some of the steps South Coast AQMD is taking to address localized impacts.

Chapter 8, “Public Process and Participation,” describes South Coast AQMD’s public outreach effort associated with development of the PM2.5 Plan.

CHAPTER 2

Air Quality

- PM2.5 concentrations were measured at 22 sites throughout the South Coast Air Basin in 2022 and have decreased significantly over the past two decades.
- PM2.5 levels are strongly influenced by meteorology, emissions of primary PM2.5 as well as the emissions of secondary PM2.5 precursors.
- While the 2022 annual PM2.5 design value exceeded the 2012 PM2.5 federal standard, the South Coast Air Basin reported the lowest annual average PM2.5 concentration in 2022 since PM2.5 monitoring began.

Introduction

In this chapter, ambient fine particulate matter (PM2.5) as monitored by South Coast AQMD is summarized for the year 2022 and prior year trends in the South Coast Air Basin (Basin). The factors influencing PM2.5 concentrations are also discussed. South Coast AQMD's recent air quality is compared to the NAAQS and to the California Ambient Air Quality Standards (CAAQS or State standards). Data presented indicate the current attainment or nonattainment status for the various NAAQS and CAAQS PM2.5 standards, showing the progress made to date and assisting the South Coast AQMD in planning for future attainment.

The South Coast AQMD began regular monitoring of PM2.5 in 1999 following the U.S. EPA's adoption of the national PM2.5 standards in 1997. In 2022, ambient PM2.5 concentrations were monitored at 22 locations throughout the South Coast Air Basin, including two near-road sites. Two types of PM2.5 sampling methods are used in the region. Federal Reference Method (FRM) samplers pull ambient air through a filter over a 24-hour period. The filter is then removed and weighed to determine ambient PM2.5 concentrations during the sampling period. The PM2.5 NAAQS are defined based on FRM measurements. The Federal Equivalent Method (FEM) samplers used by South Coast AQMD are Beta Attenuation monitors that report hourly PM2.5 concentrations continuously, which are averaged over a 24-hour period to determine daily averages. Because FRM data is the reference data for NAAQS purposes, FEM monitors undergo annual assessments by the U.S. EPA to determine their eligibility for NAAQS comparison.¹ While measurements from these two techniques produce similar concentrations, there still is some variation, with FEM samplers typically reading higher than collocated FRM samplers. ~~The PM2.5 NAAQS are defined based on FRM measurements.~~

Of the 22 monitoring stations in our region, ~~f~~Filter-based FRM PM2.5 sampling was employed at 14 of these stations. Seven of the FRM measurement stations, including the two near-road sites, were sampled daily to improve temporal coverage beyond the required 1-in-3-day sampling schedule. Eighteen stations, including two near-road sites, employed continuous PM2.5 monitors and ten of these were collocated with FRM measurements. Among the 18 stations with continuous PM2.5 monitors, seven stations utilize FEM monitors, while three stations use special purpose monitors (SPM) for continuous PM2.5 measurement. ~~FEM monitors undergo annual assessments by the U.S. EPA to determine their eligibility for NAAQS—~~ In 2021,² all FEM monitors, except for the one at the Los Angeles-North Main Street station, successfully passed the comparability assessment. Therefore, the daily averages from these monitors can be used to supplement FRM measurements on days with missing data. The SPM monitors are newly established FEM monitors that have not collected three years of data required for the NAAQS-

¹ The continuous PM2.5 monitors deployed by South Coast AQMD are FEM-designated Beta Attenuation Monitor (BAM) instruments. The U.S. EPA waiver from NAAQS compliance for the continuous samplers is re-evaluated annually as part of the South Coast AQMD Annual Air Quality Monitoring Network Plan [<http://www.aqmd.gov/home/air-quality/clean-air-plans/monitoring-network-plan>]

² At the time when this plan was drafted, the latest PM2.5 continuous monitor comparability assessment waiver approved by the U.S. EPA was for the design value period of 2019-2021

comparability assessment. They are eligible for comparison to NAAQS after they have been operated for more than 24 months unless a waiver has been granted by U.S. EPA. The continuous data is used for forecasting, real-time air quality alerts, predictive air quality advisories, and for evaluating hour-by-hour variations. Figure 2-1 provides the location of all regulatory PM_{2.5} monitors within the Basin.

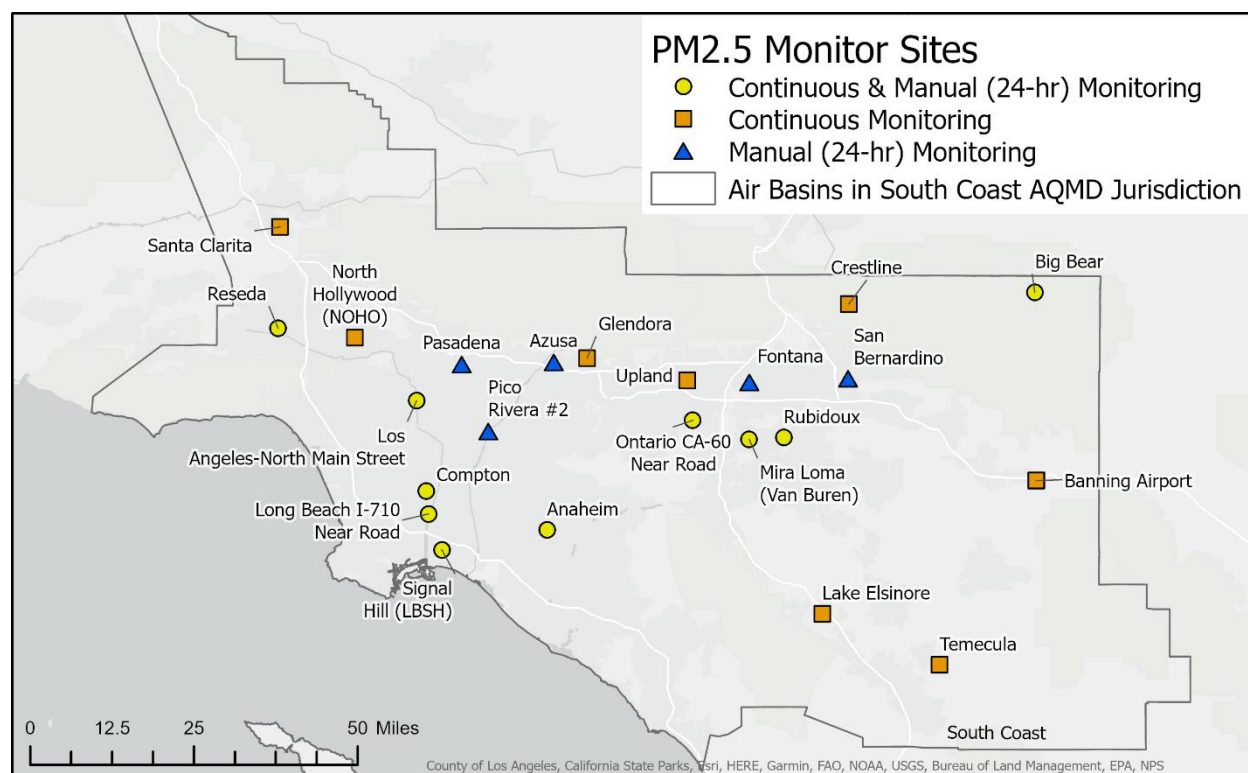

FIGURE 2-1
LOCATION OF ALL REGULATORY MONITORS IN THE SOUTH COAST AIR BASIN

Inhalation of fine particulate matter has been associated with a wide variety of health effects, including premature death. Other health impacts include exacerbation of symptoms in patients with respiratory or cardiovascular disease, decline in pulmonary function in children, increased risk of lung cancer, and potentially may be linked to adverse reproductive and cognitive effects. Some of the impacts of these health effects may be seen in increased asthma-related hospital admissions, increased school absences and lost workdays. Elevated PM_{2.5} concentrations also impair visibility. Detailed health effects information

can be found in Appendix I: Health Effects in the 2022 AQMP³ or in the U.S. EPA NAAQS documentation at <https://www.epa.gov/naaqs>.

Factors that Influence PM_{2.5} Concentrations

The South Coast Air Basin's air pollution problems are a consequence of the combination of emissions from the nation's second largest urban area, meteorological conditions that limit adverse to the dispersion of those emissions, and mountainous terrain surrounding the Basin that traps pollutants as they are pushed inland with the sea breeze. PM_{2.5} is a suspension of solid or liquid particles that are less than 2.5 micron in diameter. There are two forms of PM_{2.5} - primary and secondary. Primary PM_{2.5} particles are directly emitted by combustion sources such as vehicles, industrial processes, cooking, or fires. Secondary PM_{2.5} is formed in the atmosphere through a series of complex chemical reactions of PM_{2.5} precursors such as volatile organic compounds (VOCs), oxides of nitrogen (NO_x), and ammonia (NH₃) (Figure 2-2). The precursors that form PM_{2.5} are from mobile, point and area sources, with the largest portion resulting from fuel combustion. Both directly emitted PM_{2.5} and secondary PM_{2.5} that is formed in the atmosphere contribute to measured PM_{2.5} concentrations, but in the South Coast Air Basin, secondary PM_{2.5} formation is responsible for approximately two thirds of the total PM_{2.5} mass (Figure 2-3). Because secondary PM_{2.5} is a substantial portion of overall PM_{2.5} levels in the region, control strategies to reduce PM must address both sources of direct emissions as well as the PM_{2.5} precursors.

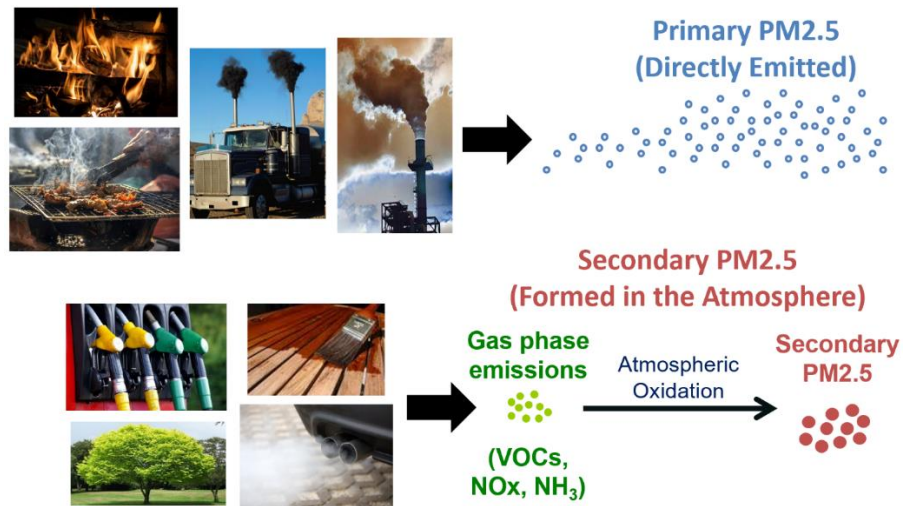

FIGURE 2-2

³ Available at www.aqmd.gov/2022aqmp

PM2.5 FORMATION MECHANISMS

FIGURE 2-3
APPROXIMATE CONTRIBUTION OF SECONDARY AND PRIMARY PM2.5 IN THE SOUTH COAST AIR BASIN⁴

Most sources of PM2.5 and PM2.5 precursors have regular patterns of emissions that may vary by time of day, day of the week or by season. However, episodes of elevated PM2.5 can be caused by emission sources that occur infrequently such as wildfires, fireworks, or residential wood combustion. Wildfires are an important source of PM2.5 and PM2.5 precursors and can lead to multiple days of high PM2.5 levels, especially during the summer and fall months when fire activity is likely. Fireworks, either from commercial displays or personal use, are a significant source of PM2.5 on July 4th and 5th each year; concentrations recorded on these days are typically the highest measured in the entire year. Residential wood combustion is also an important source of PM2.5 and PM2.5 precursors, predominantly during the months of November through February. Residents are more likely to burn wood on cool nights, on the weekends, and during holiday periods. The spatial heterogeneity in PM2.5 emissions and micro meteorology lead to significant differences in PM2.5 measurements throughout the Basin.

While long term trends in PM2.5 concentrations are largely driven by changes in emissions, the observed day to day variations in PM2.5 concentrations are primarily the result of meteorological changes except on days with elevated atypical emissions such as fireworks, wildfires, or residential wood combustion. Elevated PM2.5 concentrations can occur in the Basin throughout the year but occur most frequently in

⁴ Fractions of primary and secondary PM were estimated using the PM2.5 speciation data measured at the Los Angeles-North Main street from June 2012 to July 2018. The total mass of the elemental carbon and metals was assigned as primary PM2.5. The total mass of inorganic ions was assigned as secondary PM2.5. For organic aerosols, we referred to Figure V-6-20 in the Appendix V of the South Coast AQMD's 2016 Air Quality Management Plan (AQMP) and assigned 30 percent of the organic aerosol as primary PM2.5 and 70% to the secondary PM2.5 fraction. Appendix V of the 2016 AQMP is available at <https://www.aqmd.gov/docs/default-source/clean-air-plans/air-quality-management-plans/2016-air-quality-management-plan/final-2016-aqmp/appendix-v.pdf?sfvrsn=10>

fall and winter. This is mainly due to the unfavorable meteorological conditions that are more common in those months. Figure 2-4 summarizes the meteorological factors that influence PM_{2.5} concentrations.

FIGURE 2-4
IMPORTANT FACTORS THAT INFLUENCE PM_{2.5} CONCENTRATIONS

The average wind speed for Los Angeles is the lowest of the nation's 10 largest urban areas, resulting in reduced dispersion throughout the region. In addition, the summertime daily maximum mixing heights⁵ in Southern California are the lowest, on average, due to strong temperature inversions in the lower atmosphere that effectively trap pollutants—both primary PM_{2.5} and the PM_{2.5} precursors—near the surface. Southern California also has abundant sunshine, which drives the photochemical reactions that form secondary PM_{2.5}. Periods of fog or high humidity can also lead to elevated PM_{2.5} concentrations as chemistry in fog droplets can increase fine particle mass.

Weather disturbances and rainstorms, which predominantly occur during the winter months, are effective in reducing ambient PM_{2.5} concentrations. Enhanced ventilation and the breakup of elevated inversion layers facilitate atmospheric mixing. Rainfall is extremely effective in reducing PM_{2.5} concentrations in the atmosphere. The frequency of these disturbances can strongly influence both the 98th percentile highest daily average concentrations and the annual average concentrations, which are the key parameters to determine attainment of the 24-hour PM_{2.5} standard and the annual PM_{2.5} standard, respectively.

⁵ The maximum mixing height is an index of how well pollutants can be dispersed vertically in the atmosphere. The greater the mixing height, the greater the ventilation, and the more that pollutants are dispersed

Ambient Air Quality Standards

Federal and State Standards

Ambient air quality standards have been set by both the federal government and the State of California for fine particulate matter. In this chapter, statistics capturing the number of days exceeding federal standards are presented along with concentration trends and design values calculated from measurement data. Exceedance metrics are instructive regarding trends and control strategy effectiveness. However, it should be noted that an exceedance of the concentration level of a federal standard does not necessarily mean that the NAAQS was violated or that it would cause nonattainment. The form of the standard must also be considered. For example, for 24-hour PM_{2.5}, the form of the standard is the annual 98th percentile measurement of all the 24-hour PM_{2.5} daily samples at each station. At a station with daily measurements, this corresponds to the 8th highest daily PM_{2.5} measurement.

For PM_{2.5} NAAQS attainment/nonattainment decisions, the most recent three years of data are considered along with the form of the standard, to calculate a *design value* for each station.⁶ Design values are the statistical metrics used to compare with the NAAQS to determine attainment. The overall design value for an air basin is the highest design value of all the stations in that basin. The California State air quality standards are values not to be exceeded, typically evaluated over a three-year period, and the data is evaluated in terms of a *State Designation Value*, which allows for some statistical data outliers and exceptional events. Attainment deadlines for the State standards are ‘as soon as practicable.’

⁶ Note that for modeling attainment demonstrations, the U.S. EPA modeling guidance recommends a 5-year weighted average for the design value instead of the 3-year

**TABLE 2-1
NATIONAL AMBIENT AIR QUALITY STANDARDS (NAAQS) AND DESIGN VALUE REQUIREMENTS
FOR FINE PARTICULATE MATTER**

Averaging Time **	NAAQS Level	Design Value Form of NAAQS*
24-Hour (2006)	35 µg/m³	Three-year average of the annual 98th percentile of daily 24-hour concentration
24-Hour (1997) ***	65 µg/m ³	
Annual (2012)	12.0 µg/m³	Annual average concentration, averaged over three years <i>(annual averages based on average of 4 quarters)</i>
Annual (1997) ***	15.0 µg/m ³	
Annual (2024)****	9.0 µg/m ³	

Bold text denotes the current and most stringent NAAQS.

* The NAAQS is attained when the design value (form of concentration listed) is equal to or less than the level of the NAAQS.

** Year of U.S. EPA NAAQS update review shown in parenthesis and revoked or revised status in brackets; for revoked or revised NAAQS, areas may have continuing obligations until that standard is attained.

*** On July 25, 2016 U.S. EPA finalized a determination that the Basin attained the 1997 annual (15.0 µg/m³) and 24-hour PM_{2.5} (65 µg/m³) NAAQS, effective August 24, 2016.

**** On March 6, 2024, U.S. EPA strengthened the annual PM_{2.5} NAAQS, effective May 6, 2024.

**TABLE 2-2
CALIFORNIA AMBIENT AIR QUALITY STANDARDS (CAAQS) AND DESIGNATION VALUE
REQUIREMENTS FOR FINE PARTICULATE MATTER**

Averaging Time **	CAAQS Level	Designation Value Form of CAAQS*
Annual (2012)	12.0 µg/m ³	Annual average of the daily 24-hour concentrations. Maximum value in a three-year

* The CAAQS is attained when the designation value (form of concentration listed) is equal to or less than the level of the CAAQS.

Under the Exceptional Events Rule,⁷ U.S. EPA allows certain air quality data to not be considered for NAAQS attainment status when that data is influenced by exceptional events that meet strict evidence requirements, such as high winds, wildfires, volcanoes, or some cultural events (such as Independence Day or New Year's fireworks). An exceptional event meets the following criteria:

- The event affected air quality in such a way that there exists a clear causal relationship between the specific event and the monitored exceedance or violation;
- The event was not reasonably controllable or preventable; and
- The event was caused by human activity that is unlikely to recur at a particular location or was a natural event.

For a few PM measurements in the Basin between 2016 and 2022, the South Coast AQMD applied the U.S. EPA Exceptional Events Rule to flag these PM_{2.5} data due to wildfires and fireworks on Independence Day. All of the PM exceptional event flags through 2022 have been submitted with the affected data to U.S. EPA's Air Quality System (AQS) database. PM_{2.5} attainment designation for the South Coast Air Basin will likely depend upon U.S. EPA's concurrence with the exceptional event flags and the analysis demonstrating that exceedances were caused by wildfire smoke and/or Independence Day fireworks.

Attainment Status of the Annual PM_{2.5} Standard

The 2022 PM_{2.5} annual federal design values are summarized in Table 2-3. Data likely to be approved as exceptional events by U.S. EPA are removed from this analysis. The highest 2022 PM_{2.5} federal annual design value of 13.7 µg/m³ was measured in the Ontario CA-60 Near Road air monitoring station. The next highest 2022 PM_{2.5} federal annual design value was 13.4 µg/m³, measured in the Metropolitan Riverside County area at the Mira Loma air monitoring station.

TABLE 2-3
2020–2022 ANNUAL FEDERAL DESIGN VALUES BY COUNTY*

County	2020–2022 PM _{2.5} Annual Design Value (µg/m ³)	Percent of Current (2012) PM _{2.5} NAAQS (12.0 µg/m ³)	Area of Design Value Max
Los Angeles	13.1	109	South San Gabriel Valley
Orange	10.9**	91	Central Orange County
Riverside	13.4	112	Metropolitan Riverside County
San Bernardino	13.7	114	Ontario CA-60 Near Road

* Data likely to be approved as exceptional events by U.S. EPA removed from analysis.

** Mission Viejo in the Saddleback Valley does not have a valid design value because measurements do not meet data completeness requirements.

⁷ The Final 2016 U.S. EPA Exceptional Events Rule is available at <https://www.epa.gov/air-quality-analysis/final-2016-exceptional-events-rule-supporting-guidance-documents-updated-faqs>

The 2022 PM_{2.5} annual state designation values are summarized in Table 2-4. The 2022 PM_{2.5} annual state designation values measured in Los Angeles, Riverside, and San Bernardino Counties exceed the state standard of 12 µg/m³. The highest 2022 PM_{2.5} state annual designation value of 18 µg/m³ was measured at the Ontario CA-60 Near Road air monitoring station. State Designation Values are based on the maximum annual average recorded in the most recent three-year period, and therefore, they are less responsive to year-to-year changes in concentrations. Exceptional events were not removed when calculating these state designation values.

TABLE 2-4
2020–2022 ANNUAL STATE DESIGNATION VALUES BY COUNTY

County	2020–2022 PM _{2.5} Annual State Designation Value (µg/m ³)	Percent of Current PM _{2.5} CAAQS (12 µg/m ³)	Area of Designation Value Max
Los Angeles	16	142	East San Fernando Valley
Orange	12	100	Central Orange County
Riverside	16	142	Metropolitan Riverside County
San Bernardino	18	133	Ontario CA-60 Near Road

Figure 2-5 illustrates the spatial trend of the 2022 PM_{2.5} annual design values at all FRM PM_{2.5} stations in the South Coast Air Basin.⁸ Data likely to be approved as exceptional events by U.S. EPA are removed from Figures 2-5 and 2-6. The highest PM_{2.5} annual averages are in the inland valley areas of Riverside and San Bernardino Counties and the southern portion of Los Angeles County.

⁸ FEM PM_{2.5} data measured at Anaheim, Long Beach I-710 Near Road, Mira Loma, Ontario CA-60 Near Road, and Rubidoux stations were used to supplement missing FRM measurements

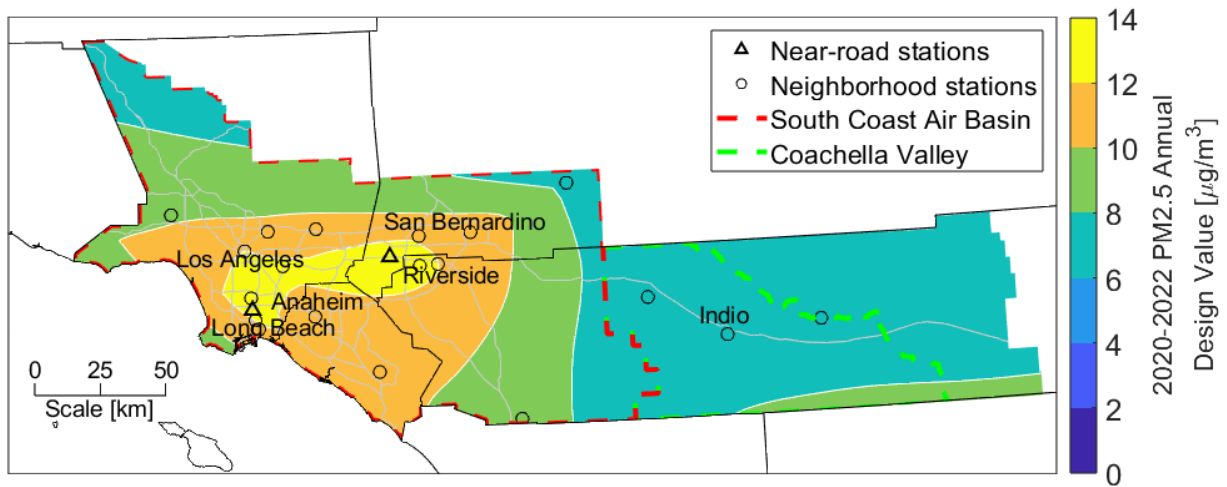

FIGURE 2-5
ALL FRM PM_{2.5} STATIONS IN THE SOUTH COAST AIR BASIN.
NEAR-ROAD STATIONS ARE SHOWN AS TRIANGLES, WHILE OTHER STATIONS ARE SHOWN
AS CIRCLES. THE COLORS REPRESENT THE 2020-2022 ANNUAL PM_{2.5} DESIGN VALUE

2022 PM_{2.5} annual design values measured at all stations with regulatory PM_{2.5} data that meet U.S. EPA completeness criteria in the South Coast Air Basin are presented in Figure 2-6. As shown in the Figure, the 2022 PM_{2.5} annual design value exceeded the federal standard at six stations: Ontario CA-60 Near Road, Mira Loma, Compton, Long Beach I-710 Near Road, Pico Rivera, and Los Angeles-North Main St., with design values of 13.7 µg/m³, 13.4 µg/m³, 13.1 µg/m³, 12.7 µg/m³, 12.5 µg/m³, and 12.1 µg/m³, respectively. These correspond to 114, 112, 109, 106, 104, and 101 percent of the annual NAAQS, respectively.

FIGURE 2-6
2020-2022 ANNUAL PM_{2.5} DESIGN VALUES MEASURED AT ALL STATIONS WITH COMPLETE DATA IN THE SOUTH COAST AIR BASIN. DATA LIKELY TO BE APPROVED AS EXCEPTIONAL EVENTS BY U.S. EPA REMOVED FROM ANALYSIS⁹

In summary, in 2022, the South Coast Air Basin ~~failed to~~ does not attain both the annual PM_{2.5} NAAQS and CAAQS. The highest PM_{2.5} annual design values for both NAAQS and CAAQS were measured at the Ontario CA-60 Near Road air monitoring station. In general, the PM_{2.5} annual averages measured in the inland valley areas of Riverside and San Bernardino Counties and the southern portion of Los Angeles County are higher than other parts of the South Coast Air Basin.

Attainment Status of the 24-hour PM_{2.5} Standard

The 2022 PM_{2.5} 24-hour design values are summarized in Table 2-2. Data likely to be approved as exceptional events by U.S. EPA are removed from this analysis. The highest 2022 PM_{2.5} 24-hour design value of 35 µg/m³ was measured in the South Central LA County area at the Compton air monitoring station and the Ontario CA-60 Near Road station. The next highest 2022 PM_{2.5} 24-hour design value was 34 µg/m³, measured in the Metropolitan Riverside County area at the Mira Loma air monitoring station. All 2022 PM_{2.5} 24-hour design values were equal or below the 24-hour NAAQS (35 µg/m³).

⁹ Long Beach (North), Long Beach (South), Azusa, and Mission Viejo stations do not have complete data in 2022 due to site closure or modification

TABLE 2-5
2020–2022 24-HOUR PM2.5 DESIGN VALUES BY COUNTY*

County	2020–2022 PM2.5 24-Hour Design Value ($\mu\text{g}/\text{m}^3$)	Percent of Current (2006) PM2.5 NAAQS ($35 \mu\text{g}/\text{m}^3$)	Area of Design Value Max
Los Angeles	35**	100	South Central LA County
Orange	30***	86	Central Orange County
Riverside	34	97	Metropolitan Riverside County
San Bernardino	35	100	Ontario CA-60 Near Road

* Data likely to be approved as exceptional events by U.S. EPA removed from analysis.

** Subject to U.S. EPA approval of a waiver to only consider more accurate filter-based measurements at Compton by excluding measurements from a continuous instrument that does not meet performance goals. In the unlikely event that U.S. EPA does not approve the waiver, the 2022 value at Compton is $37 \mu\text{g}/\text{m}^3$.

*** Mission Viejo in the Saddleback Valley area does not have a valid design value because measurements do not meet data completeness requirements.

2022 PM2.5 24-hour design values measured at all stations in the South Coast Air Basin are presented in Figure 2-7. ~~There is no state 24-hour PM2.5 standard.~~ After removing data likely to be approved as exceptional events by U.S. EPA, all stations in the South Coast Air Basin met the 24-hour federal standard by 2022. The design value at Compton is subject to U.S. EPA approval of a waiver to only consider more-accurate filter-based measurements at Compton by excluding measurements from a continuous instrument that does not meet performance goals. In the unlikely event that U.S. EPA does not approve the waiver, the 2022 design value at Compton is $37 \mu\text{g}/\text{m}^3$.

FIGURE 2-7
2020-2022 24-HOUR PM_{2.5} DESIGN VALUE MEASURED AT ALL STATIONS IN THE SOUTH COAST AIR BASIN. DATA LIKELY TO BE APPROVED AS EXCEPTIONAL EVENTS BY U.S. EPA REMOVED FROM ANALYSIS¹⁰

Figure 2-8 presents the number of days when the 24-hour PM_{2.5} exceed the 24-hour federal PM_{2.5} standard (35 µg/m³)¹¹ in each month of 2022 at each FRM PM_{2.5} station in the South Coast Air Basin. As shown in the Figure, with the exception of exceedances recorded on the fourth and fifth of July due to Independence Day fireworks, all exceedances in 2022 occur in the months of October through January. Exceedances in the winter months are predominantly caused by cold and humid weather conditions that favor the formation of secondary PM_{2.5} and emissions of residential wood smoke. Limited ventilation in the atmosphere during winter months contributes to the elevated levels of PM_{2.5} as well. Year 2022 has less PM_{2.5} 24-hour NAAQS exceedance days during the winter months (November-February) than past winter months.

¹⁰ Long Beach (North). Long Beach (South), Azusa, and Mission Viejo stations do not have complete data in 2022 due to site closure or modification

¹¹ Due to rounding conventions, the threshold to meet the 24-hour PM_{2.5} NAAQS is 35.4 µg/m³

Fairly clean period compared to past winter months.

July 4th and 5th Fireworks

THE NUMBER OF DAYS WHEN THE 24-HOUR PM_{2.5} EXCEEDED THE 24-HOUR FEDERAL PM_{2.5} STANDARD (35 MG/M³) IN EACH MONTH AT EACH FRM PM_{2.5} STATION IN THE SOUTH COAST AIR BASIN IN 2022. THE RED BOXES ARE EXCEPTIONAL EVENTS THAT ARE LIKELY TO BE APPROVED BY U.S. EPA

Historical Trends in Air Quality

Annual Standard

The historical trend of the annual average PM_{2.5} concentration measured in the South Coast Air Basin is presented in Figure 2-9. This parameter is an important metric for tracking progress towards clean air goals as the three-year average of the single year averages at each station represents the design value. As shown in the figure, the basin-maximum annual average PM_{2.5} has decreased significantly over the past two decades. The annual average recorded in 2022, which is the lowest on record, has decreased 60 percent compared with the value recorded in 2000, from 30.2 µg/m³ to 12.2 µg/m³. Between 2010 and 2015, the highest annual average PM_{2.5} concentration was recorded in Mira Loma. However, annual averages recorded at the Ontario CA-60 Near Road station exceed averages in Mira Loma since that monitor was established.

FIGURE 2-9
BASIN-MAXIMUM ANNUAL AVERAGE PM_{2.5} CONCENTRATIONS MEASURED IN THE SOUTH COAST AIR BASIN FROM 1999-2022

Historical trends in the annual PM_{2.5} design values measured in the South Coast Air Basin are shown in Figure 2-10. The annual PM_{2.5} design value has decreased significantly over the past two decades. Compared with the design value in 2001, the annual PM_{2.5} design value in 2022 decreased by 54 percent, from $29.8 \mu\text{g}/\text{m}^3$ to $13.7 \mu\text{g}/\text{m}^3$. The Ontario CA-60 Near Road station currently has the highest annual design value. By the end of 2022, the annual PM_{2.5} design value in the South Coast Air Basin is $1.7 \mu\text{g}/\text{m}^3$ higher than the 2012 annual PM_{2.5} federal standard. However, the 2022 design value is the lowest on record.

FIGURE 2-10
ANNUAL AVERAGE PM_{2.5} DESIGN VALUE IN THE SOUTH COAST AIR BASIN FROM 2000-2022

24-hour Standard

Over the past two decades, the number of 24-hour PM_{2.5} exceedance days have decreased significantly. The number of days when the basin-maximum 24-hour PM_{2.5} exceeded the 24-hour NAAQS in each month from 2000 to 2022 are shown in Figure 2-11. Among all past years on record, 2022 has the lowest number of 24-hour PM_{2.5} exceedance days. Compared with data collected in 2000, the number of days exceeding the standard in 2022 decreased by 92 percent, from 109 days to 9 days. In the early 2000s, exceedance days were recorded in every month. However, in recent years, the 24-hour standard is exceeded typically only in the colder months, from November to February, with the exception of exceedances resulting from Independence Day fireworks or wildfires.

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Total

2022	3	0	0	0	0	0	2	0	0	1	1	2	9

FIGURE 2-11

THE NUMBER OF DAYS WHEN THE BASIN-MAXIMUM 24-HOUR PM_{2.5} CONCENTRATIONS EXCEEDED THE 24-HOUR PM_{2.5} STANDARD (35 MG/M³) IN EACH MONTH FROM 2000 TO JUNE 2022 IN THE SOUTH COAST AIR BASIN

The historical trend of the basin-maximum 98th percentile 24-hour PM_{2.5} measured in the South Coast Air Basin is presented in Figure 2-12. This parameter is an important metric for tracking progress towards clean air goals as the three-year average of the 98th percentile concentration at each station represents the design value. In addition, the annual 98th percentile concentrations better capture year-to-year variations in PM_{2.5} levels. As shown in the figure, the basin maximum 98th percentile 24-hour PM_{2.5} values have declined significantly over the past two decades. The value recorded in 2019 has decreased

by 67 percent compared with the value recorded in 2000, from 85.6 $\mu\text{g}/\text{m}^3$ to 28.1 $\mu\text{g}/\text{m}^3$. With the exception of 2012, Mira Loma has had the highest 98th percentile value at all years pre-2017. Compton had the highest 98th percentile value in 2017 due to three anomalous measurements. The highest 98th percentile in the Basin in 2021 and 2022 was recorded at Pico Rivera and Fontana, respectively. However, the basin-maximum 98th percentile 24-hour PM_{2.5} measured in 2022 is the lowest on record.

* Data likely to be approved as exceptional events by U.S. EPA removed from analysis.

* Subject to U.S. EPA approval of a waiver to only consider more accurate filter-based measurements at Compton by excluding measurements from a continuous instrument that does not meet performance goals. In the unlikely event that U.S. EPA does not approve the waiver, the 2022 value is 37 $\mu\text{g}/\text{m}^3$ measured at Compton.

FIGURE 2-12
BASIN-MAXIMUM 98TH PERCENTILE 24-HOUR PM_{2.5} CONCENTRATIONS MEASURED IN THE SOUTH COAST AIR BASIN FROM 1999-2022

The historical trend of the 24-hour basin-maximum PM_{2.5} design value measured in the South Coast Air Basin is shown in Figure 2-13. After removing exceptional events occurring in 2020, the 24-hour PM_{2.5} design meets the 24-hour PM_{2.5} federal standard (35 $\mu\text{g}/\text{m}^3$) subject to U.S. EPA approval of a waiver to only consider more accurate filter-based measurements at Compton by excluding measurements from a continuous instrument that does not meet performance goals. Compared with the design value in 2001, the 24-hour PM_{2.5} design value has declined by 54 percent, from 76 $\mu\text{g}/\text{m}^3$ in 2001 to 35 $\mu\text{g}/\text{m}^3$ in 2022. From 2009 to 2016, the highest design value was recorded in Mira Loma. However, since 2018, except 2020 and 2021, Compton has replaced Mira Loma as the station with highest 24-hour PM_{2.5} design value. The elevated 24-hour PM_{2.5} design values in 2014 are due in large part to extreme drought conditions

experienced in Southern California and the associated lack of periodic storm events in the winter months that facilitate dispersion and washout of pollutants.¹²

* Data likely to be approved as exceptional events by U.S. EPA removed from analysis.

+ Subject to U.S. EPA approval of a waiver to only consider more accurate filter-based measurements at Compton by excluding measurements from a continuous instrument that does not meet performance goals. In the unlikely event that U.S. EPA does not approve the waiver, the 2022 value is 37 µg/m³ measured at Compton.

FIGURE 2-13
24-HOUR PM_{2.5} DESIGN VALUE IN THE SOUTH COAST AIR BASIN FROM 2001-2022

PM_{2.5} Speciation

Analysis of major chemical components of PM_{2.5} provides insight into the composition and sources of fine particulate matter in the Basin. These chemical components are measured through PM_{2.5} speciation samplers. Currently, PM_{2.5} speciation samplers are deployed at four representative locations in each of the Basin's counties. They are Anaheim, Fontana, Los Angeles, and Rubidoux stations. Integrated 24-hour filter samples are collected every six days and analyzed at the South Coast AQMD Laboratory. The speciation analysis presented in this chapter uses a different approach than the speciation analysis for the modeling attainment demonstration and therefore, should not be used for future projection of PM_{2.5} design values. FRM measurements that the NAAQS are based upon do not retain all the PM_{2.5} that is measured by chemical speciation samplers. Therefore, for the modeling attainment demonstration, an adjustment technique is used to estimate the species composition as measured on FRM filters to allow for

¹² 2016 South Coast AQMD Air Quality Management Plan. Available at <https://www.aqmd.gov/home/air-quality/clean-air-plans/final-2016-aqmp>

the projection of base year measurements into the future.¹³ However, the speciation analysis in this chapter uses established techniques for analyzing measured PM_{2.5} speciation data and provides valuable insight on current and past PM_{2.5} species fractions.

Figure 2-14 shows trends in average annual concentrations of six PM_{2.5} component species: elemental carbon (EC), organic matter, sulfate, nitrate, ammonium ion, and crustal material from 2010-2022. Note that data from 2020 were not included due to a 3-month hiatus in PM_{2.5} speciation sampling at the beginning of the COVID-19 pandemic. EC, sulfate, nitrate, and ammonium ion were measured directly, while organic and crustal components were calculated from measurements of organic carbon (OC) and metal concentrations, respectively, according to guidance for the U.S. EPA Chemical Speciation Network (CSN).¹⁴

Organic Matter = $1.4 \times \text{Organic Carbon}$

Crustal Material = $2.2 \times \text{Aluminum} + 2.49 \times \text{Silicon} + 1.63 \times \text{Calcium} + 2.42 \times \text{Iron} + 1.94 \times \text{Titanium}$

Annual median field blank organic carbon concentrations across the four sites were subtracted from OC measurement data to account for the well-documented positive sampling artifact caused by absorption of gas-phase OC onto filters. This correction method is similar to the current OC artifact correction method used by the Interagency Monitoring of Protected Visual Environments (IMPROVE) network and CSN, except annual field blank median concentrations were used instead of monthly medians to increase the pool of available field blank data. Furthermore, it is important to note that there is considerable uncertainty in the conversion factor between measured organic carbon and organic matter, which can range from just above 1 for organic matter with a composition close to pure carbon to greater than 2 for highly oxidized organic matter. Thus, the trend shown in Figure 2-14 is an approximation assuming the average composition of organic matter in the Basin is relatively constant.

Reported concentrations below analytical detection limits also add some uncertainty to annual average concentrations, as the true concentration for a measurement below the detection limit may range from zero to the detection limit. To account for uncertainty in non-detect concentrations, annual means for each component were calculated by substituting zero and minimum detection limit concentrations for non-detects to calculate lower and upper limit means, respectively. As shown in Figure 2-14, crustal material was the only component that was significantly affected by non-detect concentration uncertainty.

Annual mean concentrations of most components show a generally decreasing trend over the ten-year period from 2010-2022 with more muted changes from 2015-2022. The largest decrease is observed for the EC component, with average concentrations dropping by more than 50 percent at all sites from 2010 to 2022. This reduction in EC concentrations reflects the continued success of regulatory efforts to control

¹³ See https://www.epa.gov/sites/default/files/2020-10/documents/draft-o3-pm-rh-modeling_guidance-2014.pdf for details

¹⁴ <https://www.epa.gov/amtic/chemical-speciation-network-csn>

diesel emissions and other sources of EC in the Basin. In contrast to other components, average crustal concentrations remained largely similar at all sites throughout this period. Crustal material is primarily derived from windblown soil and anthropogenic sources of dust (fugitive dust, road dust, construction, etc.). These sources are generally more difficult to control and may be exacerbated by drought and other meteorological conditions. The increase of the crustal materials, EC, and organic matter in 2020 was due to the increase of wildfire activities in 2020.

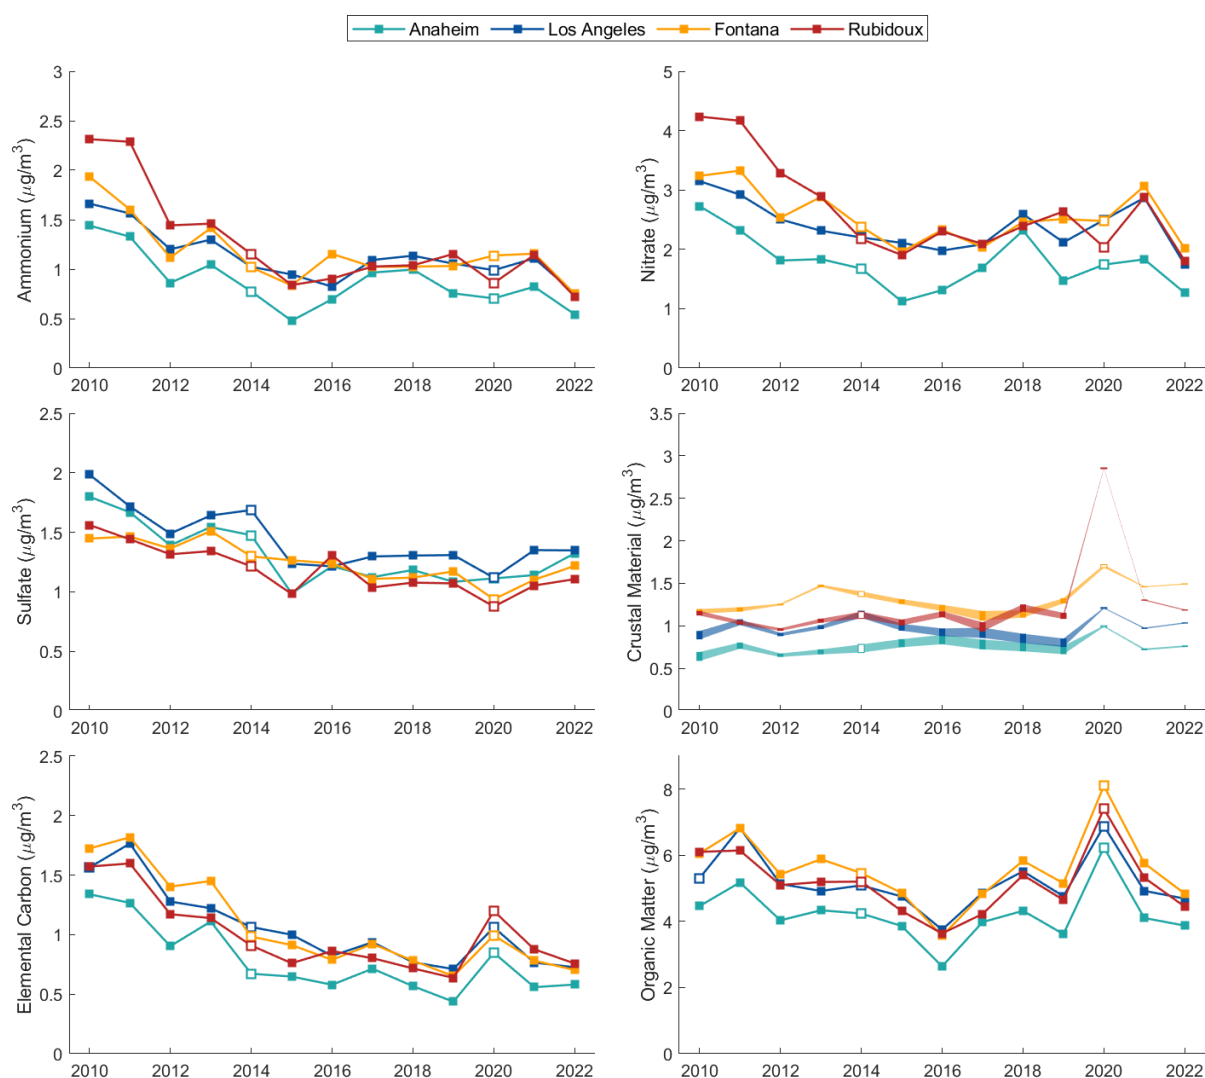

FIGURE 2-14

SOUTH COAST AIR BASIN PM_{2.5} SPECIATION NETWORK ANNUAL AVERAGE CONCENTRATION TRENDS, 2010–2022¹⁵

¹⁵ Open symbols represent years with <75 percent data completeness (67-74 percent). The uncertainty associated with concentrations below analytical detection limits is represented with shading and different sized markers for the crustal component. For all other components, this uncertainty is negligible

FIGURE 2-15
SOUTH COAST AIR BASIN PM_{2.5} SPECIATION NETWORK WEIGHTED ANNUAL AVERAGE
RELATIVE CONTRIBUTION TRENDS OF RELATIVE CONTRIBUTION TO MASS, 2010–2022¹⁶

¹⁶ Open symbols represent years with <75 percent data completeness (67-74 percent). The uncertainty associated with concentrations below analytical detection limits is represented with shading and marker size for the crustal component. For all other components, this uncertainty is negligible.

Figure 2-15 shows the annual mean contribution of each component to measured PM_{2.5} mass, weighted by total mass (i.e., days with higher PM_{2.5} have more influence on annual average). Organic matter was the dominant fraction at all sites from 2010-2022, with estimated contributions ranging from 24-54 percent of total mass. Ammonium ion and nitrate contributions to PM_{2.5} mass have generally increased from 2015-2019 after reaching their lowest levels around 2014-2015. This increasing trend is driven by both slight increases in absolute nitrate and ammonium ion concentrations as well as decreasing contributions from other species such as EC. Sulfate and crustal material contributions to total mass generally show muted changes from 2010-2022, with slight increases in crustal contributions and slight decreases in sulfate contributions observed at some sites. Due to the influence of increased wildfire activities, the fractions of crustal material, EC, and organic matter increased in 2020, while the fraction of ammonia, nitrate, and sulfate decreased compared to previous years. In 2021 and 2022, fractions of all PM_{2.5} species were similar to what was measured between 2016 and 2019.

Average seasonal concentrations of PM_{2.5} components across all sites from 2015-2022 are shown in Figure 2-16. Organic matter was the dominant component in all seasons. Both nitrate and EC concentrations and relative mass contributions peaked in the winter, while sulfate concentration and mass contribution peaked in the summer. These seasonal trends are consistent with meteorological impacts on secondary ion formation and particulate accumulation, as well as changes in seasonal PM_{2.5} emissions (i.e., residential wood burning). Other components showed more complex seasonal patterns, reflecting the competing influences of meteorology, atmospheric chemical processes, and emission patterns.

The ratio of organic carbon to elemental carbon (OC/EC) can provide further insight into the sources of organic matter in the Basin, with lower OC/EC ratios associated with primary combustion sources (e.g., diesel and gasoline combustion) and higher ratios with secondary organic formation and other OC sources. As shown in Figure 2-17, annual median OC/EC ratios show a generally increasing trend from 2010-2022, which is consistent with the steady decline in EC concentrations during this period. This trend suggests that contributions of secondary and other sources of organic matter are becoming increasingly important as diesel emissions decrease.

FIGURE 2-16
SEASONAL VARIATION IN CONCENTRATIONS OF PM_{2.5} COMPONENTS (TOP) AND RELATIVE CONTRIBUTION OF PM_{2.5} COMPONENTS TO TOTAL MASS (BOTTOM), 2015-2022¹⁷

¹⁷Winter, spring, summer, and fall are defined as DEC-FEB, MAR-MAY, JUN-AUG, SEP-NOV, respectively. The uncertainty associated with concentrations below analytical detection limits is represented with hatched shading at the top of each bar

FIGURE 2-17
TRENDS OF SOUTH COAST AIR BASIN PM_{2.5} ORGANIC CARBON (OC) TO ELEMENTAL CARBON (EC) RATIO, 2010–2022¹⁸

Summary

PM_{2.5} concentrations have declined considerably since monitoring began in the early 2000s. PM_{2.5} levels are a strong function of meteorology, emissions of primary PM_{2.5} and emissions of PM_{2.5} precursors. The 2022 24-hour PM_{2.5} design value meets the federal standard subject to removal of likely exceptional events and U.S. EPA approval of a waiver to only consider more accurate filter-based measurements at Compton by excluding measurements from a continuous instrument that does not meet performance goals. In addition, the 98th percentile PM_{2.5} values measured in 2022 were the lowest on record. While the annual PM_{2.5} design values are still above the annual standard, 2022 saw the cleanest maximum annual average PM_{2.5} level ever recorded in the South Coast Air Basin.

¹⁸ Annual median blank-corrected organic carbon to elemental carbon ratio at each site. Note that median ratios were calculated to limit effect of outliers associated with very low EC concentrations

CHAPTER 3

Emissions Inventory

- With currently adopted regulations in place, direct PM_{2.5} emissions are projected to decline 4 percent from 2018 to 2030 in the South Coast Air Basin.
- Emissions of NO_x, a PM_{2.5} precursor, are projected to decline by 45 percent, while ammonia emissions are expected to rise by 6 percent from 2018 to 2030.
- Top sources of directly emitted PM_{2.5} are from area sources and include commercial cooking, paved road dust and residential fuel combustion.
- Mobile sources continue to be the largest contributor to NO_x emissions in both 2018 and 2030.
- Ammonia emissions are forecasted to increase due to factors such as population growth and widespread use of selective catalytic reduction in heavy-duty vehicles and catalysts in light-duty vehicles.

Introduction

The South Coast Air Basin (Basin) is classified as a “serious” nonattainment area for the 2012 Annual PM2.5 standard and needs to attain the standard no later than 2030. This chapter summarizes criteria pollutant emissions from an emissions inventory in the Basin for the 2018 base year as well as projected emissions for the 2030 attainment year. A more detailed description of emissions and methodologies is presented in Appendix I.

The inventory provided here is derived from the emissions inventory developed for the 2022 Air Quality Management Plan. Major updates were introduced in on-road emissions due to the transition from EMFAC2017 to EMFAC2021, along with a minor adjustment made to construction equipment within the off-road category. This ~~Draft~~ PM2.5 Plan also includes emission estimates for filterable and condensable PM2.5 emissions. The 2018 base year emissions inventory reflects reported emissions from large facilities and estimated emissions for all other sources. The future baseline emissions inventory is based on economic projections and implementation of adopted regulations with both current and future compliance dates. A list of the South Coast Air Quality Management District (South Coast AQMD) rules and regulations that are part of the base year and future year baseline emissions inventories is presented in Appendix I. The South Coast AQMD continues to implement rules that are incorporated into the ~~Draft~~ PM2.5 Plan future baseline emissions inventories.

The emissions inventory is divided into two major source classifications: stationary and mobile sources. Stationary sources include point sources and area sources. The 2018 base year point source emissions are based principally on reported data from facilities subject to the South Coast AQMD’s Annual Emissions Reporting (AER) Program. Area source emissions are estimated jointly by CARB and the South Coast AQMD using established inventory methods. Mobile sources include on-road emissions and off-road emissions. On-road emissions are calculated using CARB’s EMFAC2021 model and travel activity data provided by the Southern California Association of Governments (SCAG) from their adopted 2020 Regional Transportation Plan/Sustainable Communities Strategy (RTP/SCS). CARB provides emissions inventories for off-road sources, which include construction and mining equipment, industrial and commercial equipment, lawn and garden equipment, agricultural equipment, ocean-going vessels (OGV), commercial harbor craft, locomotives, cargo handling equipment, pleasure craft, recreational vehicles, and fuel storage and handling. Aircraft emissions are based on an updated analysis by the South Coast AQMD developed in conjunction with commercial airports in the region.

Future emissions forecasts are primarily based on demographic and economic growth projections provided by SCAG as well as the energy consumption projections by Southern California Gas Company (SoCalGas). In addition, emission reductions resulting from the South Coast AQMD’s regulations amended or adopted by October 2020 and Rule 1109.1 and CARB regulations adopted by December 2021 are included in the future baseline projections. The South Coast AQMD’s Rule 1109.1, Emissions of Oxides of Nitrogen from Petroleum Refineries and Related Operations, was adopted in November 2021. The cutoff

dates for regulations included in the baseline emissions are the same as in the 2022 AQMP. Heavy-Duty Inspection and Maintenance (HD I/M) and Small Off-Road Engines (SORE) regulations were adopted by CARB in December 2021¹² and are reflected in the baseline emissions as well. South Coast AQMD rules that have been adopted after the cutoff dates and have NOx and PM2.5 emission reductions by 2030 are provided in Table 3-1. While these reductions are not reflected in the baseline, the reductions are included in the attainment demonstration presented in this Plan.

TABLE 3-1
RULES ADOPTED AFTER THE CUT-OFF DATE OF THE DRAFT PM2.5 PLAN FOR NON-RECLAIM
SOURCES AND NOT REFLECTED IN THE BASELINE EMISSIONS

Adoption Date	District Rule	Implementation Schedule		Net SIP Reduction by 2030* (tpd)
		Start Year	End Year	
9/1/2023	Rule 1111 – Reduction of NOx Emissions from Natural-Gas-Fired, Fan-Type Central Furnaces	2012	2050	-0.07**
5/6/2022	Rule 1147 – NOx Reductions from Miscellaneous Sources	2024	2059	0.28
8/6/2021	Rule 1147.1 - NOx Reductions from Aggregate Dryers	2025	2057	0.01
4/1/2022	Rule 1147.2 – NOx Reductions from Metal Melting and Heating Furnaces	2026	2057	0.06
2/5/2021	Rule 1150.3 – Emissions of Oxides of Nitrogen from Combustion Equipment at Landfills	2021	2031	0.04
8/4/2023	Rule 1153.1 – Emissions of Oxides of Nitrogen from Commercial Food Ovens	2024	2036	0.02
11/4/2022	Rule 1168 - VOC reductions from adhesive and sealant applications	2017	2028	-0.14**

* Net SIP Reduction represents changes in emissions with respect to the baseline inventory presented in the 2022 AQMP. Reductions by 2030 for each rule are calculated with SIP baseline inventory and associated control factors based on rule-specific implementation schedules.

**The amendment allowed more time to comply with the rule requirements, which resulted in less reductions in 2030 than the earlier version. Negative values indicate the changes from the previous version reflected in the 2022 AQMP.

¹ Heavy-Duty Inspection and Maintenance Regulation. Information available at: <https://ww2.arb.ca.gov/rulemaking/2021/hdim2021>

² Small Off-Road Engines regulations. Information available at: <https://ww2.arb.ca.gov/rulemaking/2021/sore2021>

This chapter summarizes the major components of base year and future baseline inventories. More detailed information, such as growth factors, and demographic trends, are presented in Appendix I. In addition, the top source categories contributing to the 2030 emissions inventories are described in this chapter. Understanding the highest emitting source categories assists identifying potentially more effective control strategies for improving air quality in the basin.

Emission Inventory

The inventory presented here represents annual average day emissions for the base year and future milestone years. Detailed information regarding the emissions inventory development for base and future years and emissions by major source category for the base and future milestone years are presented in Appendix I. In an emissions inventory, base year is the year from which the future emissions are projected. Pollutants reported in the inventory include volatile organic compounds (VOCs), nitrogen oxides (NO_x), carbon monoxide (CO), sulfur oxides (SO_x), ammonia (NH₃), total particulate matter (PM) and particulate matter with a diameter equal to or smaller than 2.5 microns (PM_{2.5}). Attachments A and B to Appendix I list annual average and summer planning emissions by major source category for 2018, 2025, 2028, 2030, and 2031. Attachment C to Appendix I lists the top VOC, NO_x, SO_x, NH₃ and PM_{2.5} point source facilities that emitted greater than or equal to 10 tons per year in 2018. Attachment D to Appendix I contains on-road emissions by vehicle class and pollutant. Attachment E to Appendix I shows emissions associated with diesel fuel internal combustion engines for various source categories. Attachment F to Appendix I provides a summary of road construction dust emissions in the South Coast Air Basin. Attachment G to Appendix I includes the contribution of condensable and filterable PM_{2.5} to total PM_{2.5} emissions.

Stationary Sources

Stationary sources are divided into two major subcategories: point sources and area sources. Point sources are permitted facilities with one or more emission sources at an identified location (e.g., power plants, refineries, and industrial processes factories) and subject to AER. These facilities generally have annual emissions of 4 tons or more of either VOCs, NO_x, SO_x, or PM, or annual emissions of over 100 tons of CO. Facilities are required to report their emissions of criteria pollutants and selected air toxics pursuant to Rule 301 to the South Coast AQMD on an annual basis, subject to audit, if any of these thresholds are exceeded. Point sources include emissions from the Regional Clean Air Incentives Market (RECLAIM) program, which mainly include fuel combustion emissions from power plants, oil and gas production, petroleum refining, and large facilities in manufacturing and industrial and service sectors. The 2018 annual reported emissions are used to update the stationary source inventory.

Area sources consist of many small emission sources (e.g., residential water heaters, architectural coatings, consumer products, and permitted sources that are smaller than the above thresholds) which are distributed across the basin and are not required to individually report their emissions. CARB and the South Coast AQMD jointly develop emission estimates for approximately 400 area source categories. Emissions from these sources are estimated using latest activity information and representative emission

factors if available. Activity data are usually obtained from survey data or scientific reports, e.g., U.S. Energy Information Administration (EIA) reports for fuel consumption other than natural gas fuel, natural gas consumption data from Southern California Gas Company (SoCalGas), and solvent, sealant and architectural coatings sales reports required under the South Coast AQMD Rules 314, 1113 and 1168. Some activity data, such as population, housing, and vehicle miles travelled (VMT), as well as a large portion for area sources are from SCAG. Emission factors are based on rule compliance factors, source tests, manufacturer's product or technical specification data, default factors (mostly from AP-42, the U.S. EPA's published emission factor compilation), or weighted emission factors derived from point source facilities' annual emissions reports. Additionally, emissions over a given area may be calculated using socioeconomic data, such as population, number of households, or employment in different industry sectors.

Mobile Sources

Mobile sources consist of two subcategories: on-road sources and off-road sources. On-road vehicle emissions were calculated with CARB's EMFAC2021 model and travel activity data provided by SCAG from their adopted 2020 RTP/SCS. Off-road emissions were calculated using CARB's category-specific inventory models.

On-Road

CARB's EMFAC2021 model has undergone extensive revisions from the previous version (EMFAC2017). With EMFAC2021, CARB has completed the transition from Fortran coding to Python and MySQL with the aim of maximizing user-friendliness and flexibility, allowing incorporation of larger amounts of data demanded by current regulatory and planning processes. For end users, EMFAC2021 includes a new web-based platform that includes all the features of previous EMFAC databases alongside new Project Analysis and Scenario Analysis features.

The U.S. EPA approved the EMFAC2021 emissions model for SIP and conformity purposes in November 2022.³ EMFAC2021 calculates exhaust and evaporative emission rates by vehicle type for different vehicle speeds and environmental conditions. Temperature and humidity profiles are used to produce monthly, annual, and episodic inventories. Emission rate data in EMFAC2021 is collected from various sources, such as individual vehicles in a laboratory setting, tunnel studies, and certification data. The EMFAC2021 model interface and overall design have not significantly changed as compared to EMFAC2017, however, EMFAC2021 includes more state-of-the-art information to better represent the real-world emissions from on-road sources. Major improvements include:

³ <https://www.federalregister.gov/documents/2022/11/15/2022-24790/official-release-of-emfac2021-motor-vehicle-emission-factor-model-for-use-in-the-state-of-california>

- New modules accounting for Plug-in Hybrid Electric Vehicles, vehicle energy consumption;
- Emission factors for NH₃;
- New methodologies for brake and tire wear and evaporative emissions;
- New data and significant methodology changes for motor vehicle emission calculations and revisions to implementation data for control measures;
- Updated emission factors and activity data for cars and trucks, including emission reductions associated with new regulations on heavy-heavy duty diesel trucks and buses. New emission factors were developed based on data from U.S. EPA's In-Use Vehicle Program, CARB's Vehicle and Truck and Bus Surveillance Programs, CARB's Portable Emissions Measurement Systems (PEMS) and Transit Bus testing, dynamometer and Portable Emission Measurement Systems Data;
- Expanded heavy-duty truck categories;
- New approaches to light-duty activity forecasting, using up-to-date modeling approaches from academic and government agencies to assess historic trends in multiple economic indicators to forecast future vehicle activity;
- Additional novel forecasting frameworks for heavy-duty VMT and light duty ZEV sales;
- Updated transit bus emission factors using additional data from CARB transit bus testing, and Integrated Bus Information Systems of West Virginia, and the Federal Transit Administration; and
- Updates to the motor vehicle fleet age, vehicle types, and vehicle population based on 2013-2019 California Department of Motor Vehicle (DMV) data, International Registration Plan (IRP) data, Truck Regulation Upload, Compliance, and Reporting System (TRUCRS) data, Port Vehicle Identification Number (VIN) data, California Highway Patrol School Bus Inspections, and National Transit Database information. Each of these changes affect emission factors for each area in California.

The updates in vehicle population, emission factors, and forecasting parameters included in EMFAC2021 affect the on-road emission estimates for both the 2018 base year and future years. The factors that have the greatest effect on emissions changes from EMFAC2017 to EMFAC2021 are the increase in in-use emission factors for some vehicle classes, the updated vehicle age distribution for medium-heavy duty trucks that estimates an older fleet mix with respect to EMFAC2017, and the update on brake wear emission factors based on updated measurements. More detailed information on the changes incorporated in EMFAC2021 can be found in EMFAC2021's technical documentation.⁴ The EMFAC2021 model incorporates recently adopted regulations, such as Advanced Clean Trucks (ACT),⁵ and Heavy-Duty Low NO_x Omnibus Regulations.⁶ EMFAC2021 does not incorporate Heavy-Duty Inspection and Maintenance (I/M) Regulation, because this regulation was approved after the development of

⁴ EMFAC2021 Volume III Technical Document Version 1.0.1, April 2021. Available at: https://ww2.arb.ca.gov/sites/default/files/2021-08/emfac2021_technical_documentation_april2021.pdf

⁵ Advanced Clean Trucks, <https://ww2.arb.ca.gov/our-work/programs/advanced-clean-trucks>.

⁶ Heavy-Duty Low NO_x Omnibus Regulations, Available at: <https://ww2.arb.ca.gov/rulemaking/2020/hdomnibuslownox>.

EMFAC2021. However, the effect of Heavy Duty I/M is incorporated in this plan as an external adjustment to EMFAC2021 emissions.

Figure 3-1 compares 2018 (top) and 2030 (bottom) on-road emissions estimates between the 2022 AQMP calculated using EMFAC2017 (blue) and the ~~Draft-PM2.5 plan~~Plan calculated using EMFAC2021 (green). Both estimates include the same vehicle regulations, either included in either EMFAC version, or applied as an external adjustment. For year 2018, EMFAC2021 estimates notably higher VOC and NOx emissions, and lower emissions of PM2.5 than EMFAC2017. Estimates of NOx and VOC in EMFAC2021 are higher than in EMFAC2017 because newer vehicle test data show that light-duty vehicles have higher exhaust emissions, and updated DMV data for 2018 indicate that medium heavy-duty trucks are older than what was assumed in EMFAC2017. PM2.5 emissions are substantially reduced in EMFAC2021 with respect to EMFAC2017, as a result of updates on emissions and speed correction factors for brake wear obtained from newer emission testing. The differences in VOC and PM2.5 emissions are propagated through 2030, whereas ~~NOx emissions only differ slightly between EMFAC2017 and EMFAC2021~~the differences in NOx emissions reverse in the future, showing NOx emissions estimated by EMFAC2021 slightly lower than the estimates from EMFAC2017. This reverse is because EMFAC2021 estimates higher emissions from heavy-duty vehicles in 2018 that are increasingly targeted by heavy-duty vehicle regulations in future years, resulting in steeper emission reductions by 2030. As a result, EMFAC2021 estimates lower emissions from heavy-duty vehicles compared to the estimates by EMFAC2017.

As shown on Figure 3-1 (bottom), both estimates from the 2022 AQMP using EMFAC2017 and from the PM2.5 Plan using EMFAC2021 project significantly lower emissions in the year 2030, which are attributable to the ongoing implementation of regulations and programs such as CARB's 2010 Truck and Bus rule, Advanced Clean Cars Program, Federal Phase 2 GHG Standards, Advanced Clean Truck (ACT), and Heavy-Duty (HD) Omnibus ~~low NOx requirements. Despite.~~ Accordingly, despite growth in vehicular activities, emissions from on-road mobile sources are expected to decrease in future years. Specifically, vehicle emissions under the ~~Draft-PM2.5 plan~~Plan calculated using EMFAC2021 are projected to decline from 2018 to 2030 by 49, 73, 19, and 34 percent for VOC, NOx, SOx, and PM2.5 emissions, respectively.

FIGURE 3-1
COMPARISON OF ON-ROAD EMISSIONS INCLUDED IN THE 2022 AQMP AND THE DRAFT PM2.5 PLAN.

Off-Road

Emissions from off-road vehicle categories are primarily based on estimated activity levels and emission factors using a suite of category-specific models or, where a new model was not available, the OFFROAD2007 model. Separate models have been developed for estimating emissions from different

categories of off-road mobile sources.⁷ The emissions presented here are consistent with the off-road emissions developed for the 2022 AQMP, except for a small change in construction equipment emissions. After the development of the 2022 AQMP, an error was discovered in the emission allocations for in-use emissions from off-road construction equipment in Riverside County. This error only affected future year emissions and is now corrected in this Draft PM_{2.5} Plan. As Figure 3-2 shows emissions from off-road sources in this Draft PM_{2.5} Plan remain unchanged in 2018 with respect to the 2022 AQMP, whereas there is a slight increase in emissions of VOC and NO_x in 2030.

⁷ More information on the models for offroad sources can be found in the following link:
<https://www3.arb.ca.gov/msei/msei.htm>

FIGURE 3-2
COMPARISON OF OFF-ROAD EMISSIONS BETWEEN 2022 AQMP AND DRAFT PM_{2.5} PLAN

Uncertainties in the Emissions Inventory

An effective AQMP and SIP development relies on a complete and accurate emissions inventory. Methods for quantifying different emission sources continue to improve, allowing for development of more effective control measures. Increased use of continuous monitoring and source testing has contributed to improved point source inventories. Technical assistance to facilities and auditing of reported emissions have also improved the accuracy of the emissions inventory. Area source inventories that rely on average emission factors and regional activities have inherent uncertainty. Industry-specific surveys and source-specific studies during rule development have provided much-needed refinement to these emissions estimates. Emission factors for many area sources are adapted from the U.S. EPA's AP-42, but some categories have not been updated for extended periods of time, posing additional uncertainties in estimated emissions. Mobile source inventories are also continuously updated and improved. As described earlier, many improvements are included in the on-road mobile source model EMFAC2021, which estimates emissions from trucks, automobiles, and buses. Overall, the ~~Draft~~ PM2.5 Plan is based on the most current data and methodologies, resulting in the most accurate inventory available.

There are many challenges inherent in making accurate projections based on future growth, such as where vehicle trips will occur, the distribution between various modes of transportation (such as trucks and trains), as well as estimates for population growth and the number and type of jobs. Forecasts are made with the best information available; nevertheless, there is uncertainty in emissions projections. AQMP/SIP updates are generally developed every three to four years, thereby allowing for frequent updates and improvements to the inventories.

Gridded Emissions

The air quality modeling domain extends to southern Kern County in the north, the Arizona and Nevada borders to the east, northern Mexico to the south and more than 100 miles offshore to the west. The modeling domain is divided into a grid system comprised of 4 km by 4 km grid cells. Both stationary and mobile source emissions are allocated to individual grid cells within this system. In general, emissions are modeled as total daily emissions. Variations in temperature, hours of operation, speed of motor vehicles, or other factors are considered in developing gridded motor vehicle emissions. The “gridded” emissions data used for the PM2.5 attainment demonstration differ from the annual average day inventory emission data in several ways: (1) the modeling region covers larger geographic areas than the Basin, (2) emissions represent day-specific instead of annual average conditions, and (3) emissions are adjusted with daily meteorological conditions such as temperature and humidity.

Base Year Emissions

2018 Emission Inventory

Table 3-2 compares the annual average emissions in the ~~Draft~~ PM2.5 Plan, and the emissions estimated in the 2022 AQMP for all PM2.5 precursors. As described above, the major differences between the 2022 AQMP and the ~~Draft~~ PM2.5 Plan was caused by the switch from EMFAC2017 to EMFAC2021 for on-road sources. The error in construction equipment category did not affect the base year emissions.

Overall, base year 2018 emissions of VOC, NOx and SOx in the ~~Draft~~ PM2.5 Plan are higher than in the 2022 AQMP by 4 percent, 5 percent and 1 percent, respectively. Conversely, overall PM2.5 emissions in the ~~Draft~~ PM2.5 Plan are 9 percent lower than in the 2022 AQMP.

Table 3-3 shows the 2018 annual average emissions inventory by major source category. Stationary sources are subdivided into point sources (e.g., petroleum production and electric utilities) and area sources (e.g., architectural coatings, residential water heaters, consumer products, and permitted sources smaller than the emission reporting threshold – generally 4 tons per year). Mobile sources consist of on-road (e.g., passenger cars and heavy-duty trucks) and off-road sources (e.g., locomotives and ships).

Figure 3-3 illustrates the relative contribution of each source category to the 2018 inventory. VOC and NH3 emissions are both largely driven by area sources, though specific area sources differ for the two pollutants. For VOC emissions, over half of area sources emissions are from architectural coatings and consumer products. For NH3 emissions, humans and pets contribute to half of all area source emissions. Mobile sources, stationary point source, and stationary area source categories are the top respective contributors to NOx, SOx, and PM2.5 emissions. Overall, total mobile source emissions account for almost 45 percent of VOC emissions and 85 percent of NOx emissions. The on-road mobile category alone contributes over 23 percent and 49 percent of VOC and NOx emissions, respectively. For directly emitted PM2.5, tailpipe and non-tailpipe emissions from mobile sources represent 18 percent of total emissions with an additional 15 percent from vehicle-related entrained dust from paved and unpaved roads. Stationary sources are responsible for most of the SOx emissions in the Basin, with the point source category (larger facilities subject to AER requirements) contributing 49 percent of total SOx emissions. Non-vehicle related area sources, such as commercial cooking and residential fuel combustion are the predominant source of directly emitted PM2.5 emissions, contributing 46 percent of total emissions.

Figure 3-4 shows the fraction of the 2018 inventory by responsible agency. The U.S. EPA, CARB, and South Coast AQMD split regulatory authority over these pollutants, with the U.S. EPA and CARB primarily responsible for mobile sources. Specifically, the U.S. EPA's authority applies to aircraft, locomotives, OGVs, military harbor craft, and other mobile categories, including California international registration plan (CAIRP) and out-of-state (OOS) medium- and heavy-duty trucks and pre-empt off-road equipment with less than 175 horsepower. CARB regulates other mobile sources, consumer products, and portions of area sources related to fuel combustion, and petroleum production and marketing. The South Coast AQMD

has limited authority over mobile sources, which it exercises via fleet rules and facility-based mobile source measurements. On the other hand, it exercises authority over most area sources and all point sources.

Figure 3-4 illustrates agency responsibility as it pertains to VOC, NO_x, SO_x, NH₃, and directly emitted PM_{2.5} emissions. VOC, NO_x, SO_x, NH₃ are PM_{2.5} precursors, forming secondary PM_{2.5} once emitted into the atmosphere. NO_x and VOCs are important precursors to ozone and PM_{2.5} formation. As shown, most NO_x and VOC emissions in the Basin are from sources that fall under the primary jurisdiction of the U.S. EPA or CARB. For example, 84 percent of NO_x and 74 percent of VOC emissions are from sources primarily under CARB and the U.S. EPA control. Conversely, 61 percent of SO_x emissions, 76 percent of NH₃ emissions and 81 percent of directly emitted PM_{2.5} emissions are from sources under the South Coast AQMD control. This illustrates that actions at all levels of regulatory authorities including State, and federal level are necessary to ensure that the region attains the federal ambient air quality standards.

NH3 Emissions: 75 tons/day

PM2.5 Emissions: 56 tons/day

FIGURE 3-4
2018 EMISSION INVENTORY AGENCY PRIMARY RESPONSIBILITY
(ANNUAL AVERAGE, VALUES ARE ROUNDED TO NEAREST INTEGER AND MAY NOT SUM DUE TO ROUNDING)

Future Emissions

Inventory Development

Inventories were developed for 2018, the base year, 2030, the attainment year for the 2012 annual PM_{2.5} standard of 12 µg/m³, and milestone years – 2025 and 2028– to demonstrate Reasonable Further Progress (RFP) and post attainment year, 2031. Detailed emissions inventories for all the milestone years are provided in Appendix I.

Future-year emissions were derived using: (1) emissions from the 2018 base year, (2) expected controls after implementation of the South Coast AQMD rules adopted by October 2020 and Rule 1109.1 and CARB regulations adopted by December 2021, and (3) activity growth in various source categories between the base and future years. CARB's H/D I & M was reflected in the baseline emissions as off-model adjustments as well.

Since the development of the 2022 AQMP, additional regulations pertaining to stationary sources have been implemented. These regulations affecting non-RECLAIM sources are detailed in Table 3-1, while those affecting RECLAIM sources are outlined in Table 3-4. Some regulations apply to both RECLAIM and non-RECLAIM sources, and thus, are listed in both tables. Notably, the regulations listed in Table 3-4 include those adopted prior to the October 2020 cutoff date for the 2022 AQMP. The reductions attributed to the non-shave portion of Rule 1109.1, which amount to 3.94 and 4.65 tons per day by 2030 and 2037, respectively, are already reflected in the baseline emissions (and not included in Table 3-4).

In accordance with the CMB-05 of the 2016 AQMP, multiple regulations targeting NO_x emissions were enacted to transition the RECLAIM program into a traditional command-and-control regulatory framework. A portion of the emission reductions resulting from these regulations overlapped with the RECLAIM shave, reducing the allocation cap as stipulated in Rule 2002, which was adopted in December 2015. However, the 2022 AQMP did not incorporate the reductions from the landing rules, which were intended to phase out the RECLAIM program in favor of a command-and-control structure. At the time of the 2022 AQMP development, many of these rules were still in progress, and it was uncertain whether the reductions would be considered part of the RECLAIM shave. To prevent double counting, the reductions from the landing rules were assumed to be included in the RECLAIM shave in the 2022 AQMP. Subsequently, the majority of the landing rules have been adopted, and they are expected to achieve reductions exceeding the requirements of the RECLAIM shave over a longer timeframe. As of September 2023, 11 rules have been adopted, as listed in Table 3-4, and they are anticipated to reduce NO_x emissions by 0.61 and 3.47 tons per day by 2022 and 2030, respectively. The 2022 reductions include only the rules adopted and implemented prior to 2022.

Given the maturity of the RECLAIM shave in 2022, any reductions in excess of the 2022 reductions are considered new reductions. Consequently, the net NO_x reductions from landing rules beyond the shave are projected to be 2.86 and 3.01 tons per day by 2030 and 2037, respectively. The reductions from non-

RECLAIM rules listed in Table 3-1 are 0.34 and 1.14 tons per day by 2030 and 2037, respectively. While these additional reductions are not reflected in the baseline emissions, they have been factored into the attainment and Reasonable Further Progress (RFP) demonstrations.

Furthermore, adjustments have been made to the sunset timeline for RECLAIM emissions. In the 2022 AQMP, it was assumed that 2025 and 2026 would mark the initial years without RECLAIM programs for NO_x and SO_x, respectively, based on the best available information at the time of plan development. However, during the development of the landing rules, the sunset timeline was revised, delaying the sunset of the NO_x RECLAIM program by one year and placing the sunset of the SO_x RECLAIM program on hold to accommodate operational requirements and stakeholder feedback. Consequently, for this PM_{2.5} plan, 2026 is considered the first year without the NO_x RECLAIM program, while the SO_x RECLAIM program remains in effect. To maintain transparency and consistency with emissions included in previous AQMPs and SIPs, NO_x emissions from former RECLAIM sources are provided as line-item information under “former-RECLAIM” for post-RECLAIM years.

Activity growth factors for future years are the same as the ones adopted for the 2022 AQMP. Future growth projections were based on demographic growth forecasts for various socioeconomic categories (e.g., population, housing, employment by industry) developed by SCAG for their 2020 RTP/SCS. Industry growth factors for 2030 were also provided by SCAG. Table 3-5 summarizes key socioeconomic parameters used in the Draft PM_{2.5} Plan emissions inventory development. Appendix I provides further detail on growth surrogates for different source sectors.

TABLE 3-4
RECLAIM LANDING RULES ADOPTED IN 2017 AND AFTERWARDS BUT NOT REFLECTED IN THE
BASELINE EMISSIONS OF THE DRAFT PM_{2.5} PLAN

Adopted/ Amended Date	District Rule	Implementation Schedule		Total Reductions from RECLAIM Sources in 2030 (tpd)	2030 Reduction in excess of 2022 reductions (tpd)
		Start Year	End Year		
11/1/2019	Rule 1110.2 – Control of Emissions from Gaseous- and Liquid-fueled Engines	2020	2029	0.25	0.21
1/4/2019	Rule 1118.1 – Control of Emissions from Non-Refinery Flares	2022	2025	0.03	0.03
4/5/2019	Rule 1134 – Emissions of Oxides of Nitrogen from Stationary Gas Turbines	2024	2027	1.66	1.66
11/2/2018	Rule 1135 – Electricity Generating Facilities	2020	2025	0.30	0.18
12/7/2018	Rule 1146 & 1146.1 – Emissions of Oxides of Nitrogen from Industrial, Institutional, Commercial Boilers, Steam Generators, and Process Heaters	2019	2033	0.36	0.08
12/7/2018	Rule 1146.2 – Emissions of Oxides of Nitrogen from Large Heaters and Small Boilers and Process Heaters	2022	2023	0.002	0.002
5/6/2022	Rule 1147 – NO _x Reductions from Miscellaneous Sources	2024	2059	0.40	0.40
8/6/2021	Rule 1147.1 – NO _x Reductions from Aggregate Dryers	2025	2057	0.01	0.01
4/1/2022	Rule 1147.2 – NO _x Reductions from Metal Melting and Heating Furnaces	2026	2057	0.49	0.36
8/4/2023	Rule 1153.1 – Emissions of Oxides of Nitrogen from Commercial Food Ovens	2024	2036	0.02	0.02
Cumulative reductions from the landing rules listed above*				3.47	2.86

* Reductions are calculated for each rule individually. Because some sources are affected by more than one rule, the compounded emission reductions are slightly lower than the sum of reductions from individual rules.

**TABLE 3-5
BASELINE DEMOGRAPHIC FORECASTS FOR THE SOUTH COAST AIR BASIN EMPLOYED IN THE
DRAFT-PM2.5 PLAN**

Category	2018	2030	% Growth from 2018 to 2030
Population (Millions)	16.7	18.0	7.9
Housing Units (Millions)	5.3	6.0	11.7
Total Employment (Millions)	7.7	8.3	7.3
Daily VMT (Millions)	388	395	1.8

Current forecasts indicate that this region will experience population growth of 7.9 percent between 2018 and 2030, with a 1.8 percent increase in VMT. Housing units show the largest change of the socioeconomic indicators with a projected 11.7 percent increase from 2018 to 2030.

Summary of Future Baseline Emissions

To illustrate trends in future baseline annual average inventories, emissions by source category and by pollutant for 2030 are presented in Table 3-6. Baseline inventories are projected future emissions that reflect already adopted regulations and programs but do not incorporate additional controls proposed in this Draft-PM2.5 Plan. The 2018 base year emission inventory, which captures actual 2018 emissions, is used as the basis for future projections.

Even without any additional control measures, VOC and NO_x emissions are expected to decrease due to existing South Coast AQMD and CARB regulations and programs, such as controls for on- and off-road equipment, new vehicle standards, and Rule 1109.1 for refinery emissions. For VOC and NO_x, these updated regulations result in 15 and 46 percent lower emissions in 2030 than 2018. These decreases are not uniform across sources; per Figures 3-3 and 3-5, mobile source contributions to VOC emissions decline by 45 percent but area sources, including consumer products, continue to be a significant source of VOC emissions. For NO_x emissions, amidst an overall decrease in emissions from 2018 to 2030, relative contributions change dramatically, where on-road contributions decrease from 49 to 24 percent while contributions from off-road sources increase from 36 to 54 percent. On-going implementation of adopted regulations contributes to the changes. For example, controls on heavy-duty vehicles are expected to reduce NO_x emissions significantly but could lead to increased NH₃ emissions due to ammonia slip. The contribution of on-road vehicle emissions to NH₃ increases from 22% in 2018 to 27% in 2030.

Similarly, projected economic growth results in a corresponding 3 percent projected increase in SO_x emissions. Stationary sources are projected to remain the predominant source of SO_x, with point sources

contributing almost half of total SO_x emissions in 2030. However, OGVs are significant source of SO_x emissions in the Basin, and growing shipping and OGV activity in future years is expected to increase SO_x emissions at a faster rate than growth in point source emissions, driving the 3 percent increase. The highest-ranking source categories in the 2018 and 2030 inventories are discussed in a later section.

For directly emitted PM_{2.5}, mobile sources account for 14 percent of total emissions in the 2030 inventory, a 4 percent decrease from the total mobile source contribution in 2018. This estimate excludes entrained paved/unpaved road dust sources, which shows a modest increase from 15 percent in the 2018 inventory to 17 percent in the 2030 inventory. Area sources excluding entrained paved/unpaved road dust sources are projected to remain the predominant source of directly emitted PM_{2.5}, contributing 54 percent of emissions in 2018 and 57 percent in 2030. This is mainly due to the increases in population, VMT and economic activities.

Figure 3-6 shows the fraction of the 2030 inventory by responsible agency for VOC, NO_x, SO_x, NH₃ and directly emitted PM_{2.5} emissions. In 2030, slightly larger fractions of NO_x and VOC emissions will fall under the South Coast AQMD control (31 percent for VOC and 23 percent for NO_x) due to different relative rates of emission reductions among sources controlled by the three agencies. Despite changes, the majority of VOC and NO_x emissions will remain primarily under CARB and U.S. EPA jurisdiction. NO_x sources under federal control, such as OGVs (33 tons per day), locomotives (18 tons per day), aircraft (24 tons per day), out-of-state and international heavy-duty trucks (4 tons per day), military portion of commercial harbor craft (1 ton per day), and pre-empted off-road equipment (4 tons per day) contribute ~~36~~40 percent of total NO_x emissions in the Basin in 2030, compared to ~~25~~24 percent in 2018, indicating growing disparity between regulations on federal sources and sources under State and local control. VOC emissions from consumer products, which are regulated by CARB, are projected to reach 122 tons per day in 2030, representing 39 percent of total VOC emissions in the Basin. This increase in emissions, which mostly originate from the use of personal care, hygiene, and cleaning products, reflects projected population growth in the region. The fraction of SO_x emissions that falls under the South Coast AQMD regulatory authority will remain largely unchanged from the 2018 base year inventory.

VOC Emissions: 344 tons/day

NOx Emissions: 210 tons/day

SOx Emissions: 15 tons/day

NH3 Emissions: 79 tons/day

PM2.5 Emissions: 54 tons/day

Impact of Growth

The Draft PM_{2.5} Plan forecasts the 2030 emissions inventories “with growth” through a detailed consultation process with SCAG. The region is projected to see 8 percent growth in population, 12 percent growth in housing units, 7 percent growth in employment, and 2 percent growth in VMT between 2018 and 2030. To illustrate the impact of demographic growth on emissions, “no growth” emissions were estimated by removing the growth factors from 2030 baseline emissions. Table 3-7 presents a comparison of projected 2030 emissions with and without growth. The growth impacts to 2030 VOC, NO_x, SO_x, NH₃ and directly emitted PM_{2.5} emissions are 27.5, 30.0, 1.0, 5.4, and 3.3 tons per day, respectively.

While economic growth is beneficial for the region, it presents a challenge to air quality improvement efforts as projected growth could offset the progress made in reducing VOC, NO_x, SO_x, and PM_{2.5} emissions through adopted regulations from the South Coast AQMD and CARB. Meeting the U.S. EPA’s current 2012 Annual PM_{2.5} standard of 12 µg/m³ and other NAAQS will require continued emission reduction efforts with shared responsibility from all levels of government.

**TABLE 3-7
GROWTH IMPACT TO 2030 EMISSIONS IN TONS PER DAY**

With Growth	VOC	NOX	SOX	PM2.5	NH3
Stationary Point and Area	237.4	47.8	9.0	35.8	58.0

Total	316.2	180.4	13.9	50.8	74.0
Impact of Growth	VOC	NOX	SOX	PM25	NH3
Stationary Point and Area ¹	19.8	0.4	0.2	1.9	1.9
Road Dust	0.0	0.0	0.0	0.5	0.0
On-Road	2.3	11.9	0.2	0.4	3.4
Off-Road	5.4	17.7	0.6	0.5	0.0
Total	27.5	30.0	1.0	3.3	5.4

¹ Overall growth in Electric Utilities is projected as a composite factor of employment growth, efficiency improvements and renewable portfolio standards. For this analysis, the growth portion is based on employment growth alone, which is the surrogate for overall electricity demand growth. Proposed control measures promoting zero emissions technology will increase electricity demand significantly, beyond what these baseline projections suggest.

Top Ten Source Categories in 2018 and 2030

The top ten source contributors to 2018 and 2030 annual average emissions inventories for VOC, NO_x, SO_x, directly emitted PM_{2.5} and NH₃ for years 2018 and 2030 are shown in Figures 3-7 to 3-14 and briefly discussed in this section.

Figures 3-7 to 3-8 provide the top ten source categories for VOC emissions in 2018 and 2030. These top ten categories account for approximately 82.8 and 81.5 percent of the total VOC inventories in 2018 and 2030, respectively. Consumer products, Light and Medium Duty Vehicles, and Off-Road Equipment are the three highest-emitting categories in both years. Emissions from Light and Medium Duty Vehicles and Off-Road Equipment decline substantially, which reflects the effect of regulations on vehicles and off-road equipment. On the other hand, emissions from Consumer Products, Coatings and Related Processes, and Architectural Coatings and Related Solvents emissions continue to rise due to increase in population and industrial activities.

FIGURE 3-7
TOP TEN EMITTER CATEGORIES FOR VOC IN 2018
(ANNUAL AVERAGE)

FIGURE 3-8
TOP TEN EMITTER CATEGORIES FOR VOC IN 2030
(ANNUAL AVERAGE)

Figures 3-9 to 3-10 show the top ten categories for NO_x emissions in base year 2018 and future attainment year 2030. The top ten categories account for 90.8 percent of the total NO_x inventory in 2018 and 89.6 percent in 2030. Mobile source categories remain the predominant contributor to NO_x emissions. Heavy-Duty Trucks, Light and Medium Duty Vehicles, Off-road equipment, and OGVs are the top emitters in 2018. Heavy-Duty Trucks is the top source in 2018 but their emissions are projected to decrease substantially through 2030 because of emission regulations. Other sources that are projected to decline due to regulations include Light and Medium Duty Vehicle, Off-Road Equipment and Residential Fuel Combustion. On the contrary, emissions from OGV, Aircrafts and Trains are projected to increase through 2030 driven by increases activities in those sectors.

FIGURE 3-9
TOP TEN EMITTER CATEGORIES FOR NO_x IN 2018
(ANNUAL AVERAGE)

FIGURE 3-10
TOP TEN EMITTER CATEGORIES FOR NO_x IN 2030
(ANNUAL AVERAGE)

Figures 3-11 to 3-12 show the top source categories for SO_x emissions in 2018 and 2030. The top ten categories represent approximately 92 percent of total SO_x inventory in 2018 and 2030. SO_x emissions are projected to not change substantially from 2018 to 2030. Combustion in Petroleum Refining is the largest source in the Basin in both 2018 and 2030. OGV and Aircraft are the only sources that are expected to grow due to the expected increase in activity on those sectors and the limited regulations applicable to those sources. On the other hand, regulations and turnover to cleaner vehicles result in a marginal reduction in SO_x from Light and Medium Duty Vehicles.

FIGURE 3-11
TOP EMITTER CATEGORIES FOR SO_x IN 2018
(ANNUAL AVERAGE)

FIGURE 3-12
TOP EMITTER CATEGORIES FOR SO_x IN 2030
(ANNUAL AVERAGE)

Figures 3-13 to 3-14 show the top ten source categories for annual average directly emitted PM_{2.5} in 2018 and 2030. The top 10 categories represent 76.4 percent of the total directly emitted PM_{2.5} inventory in 2018 and 78.6 percent in 2030. Commercial cooking, paved road dust, and residential fuel combustion are the largest contributors to total direct PM_{2.5} emissions. Emissions from cooking and paved road dust are projected to grow through 2030 because of the increase in population and vehicle activity. On the other hand, tailpipe emissions from vehicles are expected to decline due to vehicle emission regulations, despite the increase in vehicle miles traveled, however non-tailpipe emissions such as tire and brake wear emissions are expected to grow due to increased VMT. Emissions from residential fuel combustion are also projected to decline through 2030 due to efficiency improvements and emissions regulations, despite the increase in population. Emissions from wood and paper industries, and from construction and demolition are among the top ten sources and are expected to grow through 2030 due to the projected increase in industrial activity in those sectors.

FIGURE 3-13
TOP TEN EMITTER CATEGORIES FOR DIRECTLY EMITTED PM_{2.5} IN 2018
(ANNUAL AVERAGE)

FIGURE 3-14
TOP TEN EMITTER CATEGORIES EMITTED PM_{2.5} IN 2030
(ANNUAL AVERAGE)

Figures 3-15 to 3-16 show the top ten source categories for NH₃ emissions in 2018 and 2030. The largest source of ammonia is a group of miscellaneous sources that include human and pet perspiration. This source is expected to grow through 2030 as population grows in the basin. Emissions from vehicles are expected to grow through 2030 as well. Emissions of NH₃ from gasoline vehicles are produced as a reaction in the catalytic converter. NH₃ emitted by heavy-duty diesel trucks originates from the use of selective catalytic reactors to control NO_x emissions from diesel vehicles.⁸ The projected increase in vehicle activity for light-, medium- and heavy-duty vehicles leads to the increase in NH₃ emissions. On the other hand, emissions from farming operations are projected to decline over the years as it is projected that some farming will gradually move away from the basin.⁹

FIGURE 3-15
TOP TEN EMITTER CATEGORIES EMITTED NH₃ IN 2018
(ANNUAL AVERAGE)

⁸ Ammonia emissions from Selective Catalytic Reaction (SCR) systems is generally referred to as *ammonia slip*. SCR technology reduces NO_x emissions by converting them into harmless nitrogen and water vapor through a reaction with ammonia. However, if the SCR system injects more ammonia than required for the NO_x reduction process, or if the catalyst becomes inefficient, unreacted ammonia can escape into the exhaust stream.

⁹ Farming operations include emissions from livestock operations, with dairy cattle being the largest source in the basin. Cattle emissions are primarily based on the 2012 Census of Agriculture. Historical trends from the Santa Ana Water Control Board show a 39% decrease in the number of cows in the basin from 2008 to 2018. Growth profiles are based on CARB's projections of Census of Agriculture's historical livestock population trends, 2012. Additional information on CARB's methodology for farming operations is available at: <https://ww2.arb.ca.gov/carb-miscellaneous-process-methodologies-farming-operations>

FIGURE 3-16
TOP TEN EMITTER CATEGORIES EMITTED NH₃ IN 2030
(ANNUAL AVERAGE)

Condensable and Filterable Portions of PM_{2.5} Emissions

Per PM_{2.5} NAAQS final implementation rule,¹⁰ the SIP emissions inventory is required to identify the condensable and filterable portions of PM_{2.5} separately, in addition to primary PM_{2.5} emissions. Primary PM emissions consist of condensable and filterable portions. Condensable PM is the material that is in vapor phase in stack conditions- which then condenses to PM after cooling. Filterable PM comprises “particles that are directly emitted by a source as a solid or liquid [aerosol] at stack or release conditions.” The U.S. EPA’s Air Emissions Reporting Requirements (AERR) requires states to report annual emissions of filterable and condensable components of PM_{2.5} and PM₁₀, “as applicable,” for large sources for every inventory year and for all sources every third inventory year, beginning with 2011.¹¹ Subsequent

¹⁰ 40 CFR 51.1008(a)(1)(iv).

¹¹ 40 CFR §51.15(a)(1) and §51.30(b)(1).

emissions inventory guidance¹² from the U.S. EPA clarifies the meaning of the phrase “as applicable” by providing a list of source types “for which condensable PM is expected by the AERR.”

Category specific conversion factors developed by CARB and used in the Imperial County 2018 SIP¹³ were applied in the current analysis to estimate condensable PM and then filterable PM was calculated by subtracting the condensable from the total PM_{2.5} primary emissions. This approach is consistent with South Coast AQMD’s South Coast PM_{2.5} Plan for 2006 PM_{2.5} Standard.¹⁴ The baseline 2018, future attainment year 2030 are included in the analysis. Figure 3-17 shows the annual average emissions of primary (or direct), condensable, and filterable PM_{2.5} emissions for 2018 and 20230. Details on the condensable and filterable PM_{2.5} emissions are provided in Appendix I of this Plan.

As shown on Figure 3-17, total primary PM_{2.5} emissions increase between base and future years from 45.2 tons per day in 2018 to 46.6 tons per day in 2030. The increase in total primary PM_{2.5} appears in both condensable and filterable portions with 0.8 tons per day and 0.6 tons per day increase, respectively, between 2018 and 2030. These increases can be attributed to the growth in population and economic activities in the Basin.

FIGURE 3-17
ANNUAL AVERAGE PRIMARY, FILTERABLE AND CONDENSABLE PM_{2.5} EMISSIONS FROM STATIONARY SOURCES

¹³ Imperial County 2018 Annual Particulate Matter less than 2.5 microns in Diameter State Implementation Plan, April 2018. Available at https://ww3.arb.ca.gov/planning/sip/planarea/imperial/final_2018_ic_pm25_sip.pdf.

¹⁴ Available at <http://www.aqmd.gov/docs/default-source/clean-air-plans/air-quality-management-plans/2022-air-quality-management-plan/2-final-attainment-plan-for-2006-24-hour-pm2-5-standard-for-the-south-coast-air-basin.pdf?sfvrsn=6>

Table 3-8 presents the top five source categories for condensable PM_{2.5} in 2018 and future milestone years. The majority of condensable PM_{2.5} is emitted from the “Cooking” category, which accounts for 75.1 percent and 76.8 percent of the total condensable PM_{2.5} in 2018 and 2030, respectively. The sum of the top five condensable PM_{2.5} categories represents 95.7 percent and 95.9 percent of the total condensable PM_{2.5} both in 2018 and 2030, respectively. Table 3-9 shows the top five categories for filterable PM_{2.5}. The “Paved Road Dust” source category is the top emitter of filterable PM_{2.5}. The top five filterable PM_{2.5} emissions categories account for approximately 70.7 percent (2018) and 72.9 percent (2030) of the total filterable PM_{2.5} emissions. This points to a marginally higher contribution of top five filterable categories to total filterable PM_{2.5} emissions in future years. Detailed emissions by major source category are included in Appendix I of this Plan.

TABLE 3-8
TOP 5 CATEGORIES EMITTING CONDENSABLE PM_{2.5} (TONS PER DAY)

Category	2018	2030

CHAPTER 4

Control Strategy

- The bulk of the emission reductions needed to attain the 2012 annual PM2.5 standard will come from continued implementation of already adopted rules and regulations.
- The PM2.5 Plan advocates for a control strategy aimed at expediting implementation of 2022 AQMP NOx measures, leveraging PM2.5 co-benefits from these NOx measures, and reducing ammonia and direct PM2.5 emissions through selected controls mandated by the U.S. EPA.
- The control strategy complies with U.S. EPA's requirements including Best Available Control Measures and Most Stringent Measures.

Introduction

The control strategy in the South Coast Air Basin Attainment Plan for the 2012 Annual PM2.5 Standard provides the path to achieving the emission reductions needed to meet the 2012 annual PM2.5 NAAQS. Implementation of the PM2.5 Plan will be based on a series of control measures and strategies that vary by source type (i.e., stationary or mobile) as well as by pollutant, i.e., NOx, ammonia (NH3), or direct PM2.5. This chapter outlines the proposed control strategy and the schedules to adopt and implement the PM2.5 Plan to meet the 2012 annual PM2.5 standard in the South Coast Air Basin (Basin). The PM2.5 Plan control strategy includes a variety of implementation approaches such as regulation, accelerated deployment of available cleaner technologies, best management practices, co-benefits from existing programs (e.g., climate and energy efficiency), and incentives. Table 4-1 provides an overview of the criteria used in evaluating and selecting feasible control measures.

TABLE 4-1
CRITERIA FOR EVALUATING THE PM2.5 PLAN CONTROL MEASURES (LISTED ALPHABETICALLY)

Criteria	Description
Cost-Effectiveness	The cost of a control measure per reduction of emissions of a particular pollutant (cost includes purchasing, installing, operating, and maintaining the control technology).
Emission Reduction Potential	The total amount of pollution that a control measure can reduce.
Enforceability	The ability to ensure compliance with a control measure.
Legal Authority	Ability of the South Coast AQMD or other adopting agency to legally implement the measure.
Public Acceptability	The likelihood that the public will approve or cooperate in the implementation of a control measure.
Rate of Emission Reduction	The time it will take for a control measure to reduce a certain amount of air pollution.
Technological Feasibility	The likelihood that the technology for a control measure is or will be available.

Overall Strategy

The PM2.5 Plan relies primarily on previously adopted control measures from the 2022 AQMP and the 2022 State SIP Strategy. The Plan also relies on limited new controls for directly-emitted PM2.5 and key precursor pollutants, including NOx and NH3. By 2030, directly-emitted PM2.5 needs to be reduced by 6

percent from 2018 levels and NO_x needs to be reduced by 54 percent. Although emissions of NH₃ will increase by 2 percent over this timeframe, the Basin is still expected to meet the standard by 2030.

NO_x is the primary precursor that will have the most impact on reducing PM_{2.5} levels in the Basin between 2018 and 2030. Approximately 383 tons per day of Basin total NO_x emissions in 2018 need to be reduced to 176 tons per day by 2030. Continued implementation of adopted rules and regulations (i.e., baseline measures) are already projected to decrease emissions to 210 tons per day by the 2030 attainment year. Control measures included in this Plan are projected to reduce an additional 10 tons per day of NO_x by 2030 and recently adopted regulations not included in the baseline will further reduce NO_x emissions by 25 tons per day.

The 2022 AQMP and 2022 State SIP strategy were focused on reducing ozone levels, and its control measures therefore maximized NO_x emission reductions. ~~The se Plans~~ overall approach of these plans requires broad adoption of zero emission technologies across all emission sources when cost-effective and feasible, and low NO_x emission technologies where zero emission technologies are not yet feasible – all with a goal of achieving federal ozone standard by 2037. Selected 2022 AQMP and 2022 State SIP Strategy measures with potential NO_x emission reductions that can be achieved by 2030 are included in the PM_{2.5} Plan and directly-emitted PM_{2.5} co-benefits have been quantified.

The PM_{2.5} Plan also includes limited strategies to reduce directly-emitted PM_{2.5} and NH₃ emissions to assist with attainment and to fulfill CAA requirements. If only baseline measures are considered, directly-emitted PM_{2.5} emissions are projected to decrease from 56 tons per day in 2018 to 54 tons per day in 2030 while NH₃ emissions are projected to increase from 75 tons per day in 2018 to 79 tons per day in 2030. Recently adopted regulations not included in the baseline will reduce directly-emitted PM_{2.5} and NH₃ emissions by 0.83 tons per day and 2.96 tons per day, respectively, by 2030. Control measures proposed in this Plan seek to lower directly-emitted PM_{2.5} and NH₃ emissions by an additional 0.54 tons per day and 0.25 tons per day, respectively, by 2030.

In addition to implementing a control strategy for attainment, the PM_{2.5} Plan is required to satisfy U.S. EPA's requirements including Best Available Control Measures (BACM) and Most Stringent Measures (MSM). Demonstrating compliance with BACM and MSM requirements is independent of attainment and therefore some control measures are included which are not needed for attaining the standard. For details on the BACM and MSM requirements and analysis, refer to Appendix III.

South Coast AQMD Proposed Annual PM_{2.5} Strategy

South Coast AQMD's proposed annual PM_{2.5} attainment strategy consists of two parts: stationary source measures and mobile source measures. In this PM_{2.5} Plan, the South Coast AQMD is proposing a total of 38 control measures. Only one of these measures is new and not carried over from the 2022 AQMP or the 2016 AQMP. Out of the 38 proposed control measures, 23 measures target reductions from stationary sources and the remaining 15 measures target reductions from mobile sources.

South Coast AQMD Proposed Stationary Source Measures

A control measure is a set of specific technologies and methods identified for potential implementation to reduce emissions to attain an air quality standard. The proposed stationary source PM2.5 measures are designed to assist with attainment of the 2012 annual PM2.5 standard primarily through NOx emission reductions with concurrent NH3 and direct PM2.5 reductions. Co-benefits from GHG emission reduction policies and other measures are included as well.

Stationary source measures include Best Control Measures (BCM) that seek to reduce NOx emissions from residential and large industrial combustion sources, NH3 emissions from livestock waste and greenwaste disposal, and direct PM2.5 emissions from combustion and non-combustion sources. Some of the NOx measures pursue co-benefits from Energy and Climate Change Programs (ECC) measures and from other BCM measures. While all control measures seek to reduce emissions, not all measures have quantified reductions. The majority of stationary source measures are anticipated to be developed in the next several years and implemented in whole or in part prior to 2030.

Table 4-2 provides a list of the South Coast AQMD proposed PM2.5 measures for stationary sources along with anticipated emission reductions in 2030. The following sections provide a brief description of the proposed stationary source measures. Detailed descriptions of the measures are provided in Appendix IV-A.

TABLE 4-2
SOUTH COAST AQMD PROPOSED STATIONARY SOURCE MEASURES

Number	Title [Pollutant]	Previous Plan Measure Was Included	Emission Reductions (2030) (tons per day)
South Coast AQMD Stationary Source NOx Measures:			
BCM-01	Emission Reductions from Replacement with Zero Emission or Low NOx Appliances – Residential Water Heating* [PM2.5, NOx]	2022 AQMP (R-CMB-01)	TBD
BCM-02	Emission Reductions from Replacement with Zero Emission or Low NOx Appliances – Residential Space Heating* [PM2.5, NOx]	2022 AQMP (R-CMB-02)	TBD
BCM-03	Emission Reductions from Residential Cooking Devices [PM2.5, NOx]	2022 AQMP (R-CMB-03)	TBD
BCM-04	Emission Reductions from Replacement with Zero Emission or Low NOx Appliances – Residential Other Combustion Sources [PM2.5, NOx]	2022 AQMP (R-CMB-04)	TBD

Number	Title [Pollutant]	Previous Plan Measure Was Included	Emission Reductions (2030) (tons per day)
BCM-05	Emission Reductions from Emergency Standby Engines [PM2.5, NOx]	2022 AQMP (L-CMB-04)	0.04 [PM2.5] 0.36 [NOx]
BCM-06	Emission Reductions from Diesel Electricity Generating Facilities [NOx]	2022 AQMP (L-CMB-06)	0.16
BCM-07	Emission Reductions from Incinerators [NOx]	2022 AQMP (L-CMB-09)	0.81
	Total Quantified PM2.5 and NOx Reductions		0.04 [PM2.5] 1.33 [NOx]
South Coast AQMD Co-Benefits from Energy and Climate Change Programs Measures:			
ECC-01	Co-benefits from Existing and Future Greenhouse Gas Programs, Policies, and Incentives [All Pollutants]	2022 AQMP (ECC-01)	TBD
ECC-02	Co-benefits from Existing and Future Residential and Commercial Building Energy Efficiency Measures [All Pollutants]	2022 AQMP (ECC-02)	TBD
ECC-03	Additional Enhancements in Reducing Existing Residential Building Energy Use [All Pollutants]	2022 AQMP (ECC-03)	TBD
South Coast AQMD NH3 Measures:			
BCM-08	Emission Reductions from Livestock Waste at Confined Animal Facilities* [NH3]	2016 AQMP (BCM-04)	0.27
BCM-09	Ammonia Emission Reductions from NOx Controls [NH3]	2016 AQMP (BCM-05)	TBD
BCM-10	Emission Reductions from Direct Land Application of Chipped and Ground Uncomposted Greenwaste* [NH3]	2016 AQMP (BCM-10)	0.08
BCM-11	Emission Reductions from Organic Waste Composting [NH3]	2016 AQMP (BCM-10)	TBD
	Total Quantified NH3 Reductions		0.35
South Coast AQMD Direct PM2.5 Measures:			
BCM-12	Further Emission Reductions from Commercial Cooking* [PM2.5]	2016 AQMP (BCM-01)	TBD

Number	Title [Pollutant]	Previous Plan Measure Was Included	Emission Reductions (2030) (tons per day)
BCM-13	Emission Reductions from Cooling Towers [PM _{2.5}]	2016 AQMP (BCM-02)	TBD
BCM-14	Further Emission Reductions from Paved Road Dust Sources [PM _{2.5}]	2016 AQMP (BCM-03)	TBD
BCM-15	Emission Reductions from Abrasive Blasting Operations [PM _{2.5}]	2016 AQMP (BCM-06)	TBD
BCM-16	Emission Reductions from Stone Grinding, Cutting and Polishing Operations [PM _{2.5}]	2016 AQMP (BCM-07)	TBD
BCM-17	Emission Reductions from Prescribed Burning for Wildfire Prevention [PM _{2.5}]	2022 AQMP (MCS-02)	TBD
BCM-18	Further Emission Reductions from Wood-Burning Fireplaces and Wood Stoves* [PM _{2.5}]	2016 AQMP (BCM-09)	TBD <u>0.33</u>
BCM-19	Emission Reductions from Unpaved Road Dust Sources [PM _{2.5}]	New	TBD
	Total Quantified Direct PM_{2.5} Reductions		TBD <u>0.33</u>
South Coast AQMD Other Measures:			
BCM-20	Application of All Feasible Measures [All Pollutants]	2022 AQMP (MCS-01)	TBD

* These measures are included to satisfy MSM requirements.

Note: TBD are reductions to be determined once the measure is further evaluated, the technical assessment is complete, and inventories and cost-effective control approaches are identified, and are not relied upon for attainment demonstration purposes.

South Coast AQMD Stationary Source NO_x Measures

There are seven NO_x measures as listed below:

- BCM-01: Emission Reductions from Replacement with Zero Emission or Low NO_x Appliances – Residential Water Heating
- BCM-02: Emission Reductions from Replacement with Zero Emission or Low NO_x Appliances – Residential Space Heating

- BCM-03: Emission Reductions from Residential Cooking Devices
- BCM-04: Emission Reductions from Replacement with Zero Emission or Low NOx Appliances – Residential Other Combustion Sources
- BCM-05: Emission Reductions from Emergency Standby Engines
- BCM-06: Emission Reductions from Diesel Electricity Generating Facilities
- BCM-07: Emission Reductions from Incinerators

BCM-01: EMISSION REDUCTIONS FROM REPLACEMENT WITH ZERO EMISSION OR LOW NOX APPLIANCES – RESIDENTIAL WATER HEATING: This control measure, based on 2022 AQMP control measure R-CMB-01, seeks to reduce NOx emissions from residential building water heating sources that are subject to Rule 1121 – Control of Oxides of Nitrogen (NOx) from Residential Type, Natural Gas-Fired Water Heaters. The measure proposes to: (1) develop a rule to require zero emission water heating units for installations in both new and existing residences; and (2) allow low NOx technologies as a transitional alternative when installing a zero emission unit is determined to be infeasible (e.g., colder climate zones, or architecture design obstacles). This control measure would include incentive funds to facilitate the transition to zero emission technologies and promote further emission reductions earlier than required.

BCM-02: EMISSION REDUCTIONS FROM REPLACEMENT WITH ZERO EMISSION OR LOW NOX APPLIANCES – RESIDENTIAL SPACE HEATING: This control measure, based on 2022 AQMP control measure R-CMB-02, seeks to reduce NOx emissions from residential space heating sources regulated by Rule 1111 – Reduction of NOx Emissions from Natural-Gas-Fired, Fan-Type Central Furnaces. The measure proposes to: (1) develop a rule to require zero emission space heating units for installations in both new and existing residences; and (2) allow low NOx technologies as a transitional alternative when installing a zero emission unit is determined to be infeasible. This control measure would also provide incentive funds to facilitate adoption of zero emission technologies that would promote further emission reductions earlier than required.

BCM-03: EMISSION REDUCTIONS FROM RESIDENTIAL COOKING DEVICES: This control measure, based on 2022 AQMP control measure R-CMB-03, seeks to reduce NOx emissions from residential cooking devices including stoves, ovens, griddles, broilers, and others in new and existing buildings. Replacing the existing gas burners with electric cooking devices, induction cooktops, or low NOx gas burner technologies will reduce NOx emissions. NOx reductions will be pursued through a combination of regulatory approaches and incentives, and/or efficiency standards. Proposed method of control consists of two steps. Step one includes a technology assessment of emissions testing of various cooking devices to establish emissions rates. Once emissions rates are defined, step two supports future rule development and incentive programs. The rule would apply to manufacturers, distributors, and installers establishing emission limits. The incentive programs would provide funds to encourage and promote adoption of zero and low NOx emission technologies.

BCM-04: EMISSION REDUCTIONS FROM REPLACEMENT WITH ZERO EMISSION OR LOW NOX APPLIANCES – RESIDENTIAL OTHER COMBUSTION SOURCES: This control measure, based on 2022 AQMP control measure R-CMB-04, seeks to reduce NOx emissions from residential combustion sources that are not water heating (See BCM-01), space heating (See BCM-02) and cooking equipment (See BCM-03). BCM-04 sources are miscellaneous, but primarily comprised of natural gas and liquified petroleum gas (LPG) fired swimming pool heaters, laundry dryers, and barbecue grills. The measure proposes to: (1) develop a rule to require zero emission technologies for some emission sources in both new and existing residences; and (2) allow low NOx technologies as an alternative for the rest of emission sources. Mitigation fees may be required for certain lower NOx technology applications which will be evaluated during the future rulemaking process. During the rulemaking, staff will assess the universe of equipment. Incentive funds will be considered to facilitate adoption of zero emission technologies that would promote further emission reductions earlier than required.

BCM-05: EMISSION REDUCTIONS FROM EMERGENCY STANDBY ENGINES: South Coast AQMD regulations require permits for stationary Internal Combustion Engines (ICEs) rated over 50 brake horsepower. The permits currently limit emergency standby ICE usage to less than 200 hours per year which includes a limit of 20 to 50 hours for maintenance and testing purposes. Rule 1470 requires the use of CARB diesel fuel for all diesel-fueled ICEs rated over 50 brake horsepower. This control measure, based on 2022 AQMP control measure L-CMB-04, seeks to maximize PM2.5 and NOx emission reductions by requiring the use of renewable diesel as a drop-in replacement for CARB diesel fuel for all emergency standby ICEs that are not equipped with Tier 4 Final controls.

BCM-06: EMISSION REDUCTIONS FROM DIESEL ELECTRICITY GENERATING FACILITIES: This control measure, based on 2022 AQMP control measure L-CMB-06, seeks to reduce NOx emissions from electric generating units regulated by Rule 1135 – Emissions of Oxides of Nitrogen from Electricity Generating Facilities. This measure proposes to implement low NOx and zero emission technologies and to require the use of renewable diesel in engines used for backup power. The target of this approach is to replace existing diesel internal combustion engines with lower-emitting technologies and utilize renewable diesel for fueling the remaining diesel engines used for backup power.

BCM-07: EMISSION REDUCTIONS FROM INCINERATORS: This control measure, based on 2022 AQMP control measure L-CMB-09, seeks emission reductions of NOx by replacement or retrofits with low NOx emission technologies on incinerators and other combustion equipment associated with incinerators and better control of NH3 injection used to control NOx. The South Coast AQMD has adopted a series of rules to promote clean, lower emission technologies, while encouraging economic growth and providing compliance flexibility. Burner technologies and combustion controls are utilized to reduce NOx emissions. The target of this approach is to reduce ammonia emissions by utilizing a closed loop feed-forward control system and reduce NOx emissions with improved burner technologies.

South Coast AQMD Co-Benefits from Energy and Climate Change Programs Measures

There are three energy and climate change programs co-benefit measures as listed below:

- ECC-01: Co-Benefits from Existing and Future Greenhouse Gas Programs, Policies, and Incentives
- ECC-02: Co-Benefits from Existing and Future Residential and Commercial Building Energy Efficiency Measures
- ECC-03: Additional Enhancements in Reducing Existing Residential Building Energy Use

ECC-01: CO-BENEFITS FROM EXISTING AND FUTURE GREENHOUSE GAS PROGRAMS, POLICIES, AND INCENTIVES: This control measure, based on 2022 AQMP control measure ECC-01, seeks to quantify and take credit for the criteria pollutant co-benefits associated with programs to reduce GHG emissions. The processes that emit criteria pollutants and their precursors also typically emit GHGs. Mandates and programs that reduce GHG emissions will therefore also reduce criteria pollutant emissions. Significant efforts are currently being planned and implemented to reduce GHG emissions under State programs such as California Governor Executive Order B-55-18 and SB 100 (California Renewables Portfolio Standard Program: Emissions of Greenhouse Gases), which established reduction goals for 2030, 2045, and 2050.

ECC-02: CO-BENEFITS FROM EXISTING AND FUTURE RESIDENTIAL AND COMMERCIAL BUILDING ENERGY EFFICIENCY MEASURES: This control measure, based on 2022 AQMP control measure ECC-02, seeks to quantify and take credit for criteria pollutant co-benefits resulting from the implementation of energy efficiency mandates such as California's Title 24 program. In addition, there are multiple programs that provide incentives, rebates, and loans for residential and commercial building efficiency projects. Improvements in weatherization and other efficiency measures provide emission reductions through reduced energy use for heating, cooling, lighting, cooking, and other needs. South Coast AQMD staff will work with agencies, utilities, and other stakeholders to implement innovative measures that provide energy savings along with emission reductions.

ECC-03: ADDITIONAL ENHANCEMENTS IN REDUCING EXISTING RESIDENTIAL BUILDING ENERGY USE: This control measure, based on 2022 AQMP control measure ECC-03, seeks to provide incentive funding to enhance the objectives of ECC-02. Incentives will be used to further promote programs reducing energy use associated with space heating, water heating, and other large residential energy sources, achieving emission reductions beyond the levels expected from program mandates. Residential incentive programs would be developed to facilitate weatherization, replace older appliances with highly efficient technologies and encourage renewable energy adoption. Incorporating efficient appliance technologies, improving weatherization, and encouraging renewables such as solar thermal and photovoltaics will reduce energy demand and provide additional emission reductions within the residential sector. The South Coast AQMD will collaborate with utilities, agencies, and organizations to help leverage funding and coordinate incentives with existing programs.

South Coast AQMD Stationary Source NH₃ Measures

There are four NH₃ measures as listed below:

- BCM-08: Emission Reductions from Livestock Waste at Confined Animal Facilities
- BCM-09: Ammonia Emission Reductions from NO_x Controls
- BCM-10: Emission Reductions from Direct Land Application of Chipped and Ground Uncomposted Greenwaste
- BCM-11: Emission Reductions from Organic Waste Composting

BCM-08: EMISSION REDUCTIONS FROM LIVESTOCK WASTE AT CONFINED ANIMAL FACILITIES: This control measure seeks to reduce NH₃ emissions from livestock waste at large Confined Animal Facilities (CAFs). The first approach aims to lower the applicability thresholds in South Coast AQMD Rule 223 to align with the more stringent thresholds in San Joaquin Valley Air Pollution Control District (SJVAPCD) Rule 4570 – Confined Animal Facilities. The second approach aims to introduce additional mitigation measures to reduce ammonia emissions at CAFs.

BCM-09: AMMONIA EMISSION REDUCTIONS FROM NO_x CONTROLS: This control measure seeks to reduce NH₃ emissions from NO_x controls such as Selective Catalytic Reduction (SCR) and Selective Non-Catalytic Reduction (SNCR). These systems are capable of effectively reducing NO_x emissions from combustion sources. However, their use also results in potential emissions of NH₃ that “slip” past the control equipment and into the atmosphere. Upgraded SCRs can be tuned/optimized by improving the Ammonia Injection Grid (AIG) to achieve the required NO_x limits and simultaneously reduce the NH₃ slip.

BCM-10: EMISSION REDUCTIONS FROM DIRECT LAND APPLICATION OF CHIPPED AND GROUND UNCOMPOSTED GREENWASTE: This control measure seeks reductions in NH₃ emissions from direct land application (DLA) of chipped and ground uncomposted greenwaste to agricultural land, public land for erosion control or roadway management, and consumers’ properties for gardening or landscaping purposes. This control measure proposes to require composting of chipped and ground greenwaste, in accordance with the Best Management Practices (BMP) requirements of Rule 1133.3, prior to DLA.

BCM-11: EMISSION REDUCTIONS FROM ORGANIC WASTE COMPOSTING: This control measure seeks emission reductions of NH₃ from the processing of organic waste materials including foodwaste, greenwaste, and agricultural waste. Control approaches include foodwaste co-digestion and integration of anaerobic digestion (AD) with composting. If foodwaste is the only feedstock input to AD, the resulting digestate could be included into greenwaste composting where emission control is governed by Rule 1133.3. This control measure proposes to expand the applicability of Rules 1133.2 and 1133.3 to regulate the co-digestion of foodwaste with biosolids and the integration of foodwaste digestate with greenwaste composting for further emission reductions. An integrated AD-composting system will result in less overall waste and a more useful product.

South Coast AQMD Stationary Source Direct PM_{2.5} Measures

There are eight direct PM_{2.5} measures as listed below:

- BCM-12: Further Emission Reductions from Commercial Cooking
- BCM-13: Emission Reductions from Cooling Towers
- BCM-14: Further Emission Reductions from Paved Road Dust Sources
- BCM-15: Emission Reductions from Abrasive Blasting Operations
- BCM-16: Emission Reductions from Stone Grinding, Cutting and Polishing Operations
- BCM-17: Emission Reductions from Prescribed Burning for Wildfire Prevention
- BCM-18: Further Emission Reductions from Wood-Burning Fireplaces and Wood Stoves
- BCM-19: Emission Reductions from Unpaved Road Dust Sources

BCM-12: FURTHER EMISSION REDUCTIONS FROM COMMERCIAL COOKING: This control measure seeks emission reductions from commercial cooking by lowering the applicability threshold for chain-driven charbroilers in Rule 1138. Other actions may be pursued such as revising the emissions inventory for charbroilers and evaluating the feasibility of under-fired control technology. The current emissions inventory for this category is based on a restaurant survey conducted in 1998, indicating the need for an update. A charbroiler registration program and/or survey may be considered to assist with revising the inventory. Additionally, projects to develop economically viable under-fired charbroiler control technology and pilot studies to test the efficacy of such control technologies will be considered.

BCM-13: EMISSION REDUCTIONS FROM INDUSTRIAL COOLING TOWERS: This control measure seeks reductions of PM emissions from industrial process cooling towers with drift eliminator technologies used for a variety of industrial operations including power plants, petroleum refineries, petrochemical plants, and natural gas processing plants. Prior to developing a policy to implement controls, an emissions inventory and an equipment universe must be established. Registration submittals collected through Rule 222 – Filing Requirements for Specific Emission Sources Not Requiring a Written Permit Pursuant to Regulation II, may be used as a starting point to develop an equipment universe.

BCM-14: FURTHER EMISSION REDUCTIONS FROM PAVED ROAD DUST SOURCES: Existing South Coast AQMD regulations implement paved road dust controls based on U.S. EPA guidance through both preventative and mitigative controls such as street sweeping. Mandating increased street sweeping frequencies has unknown impacts on PM_{2.5} levels and studies that examine the effect of street sweeping on ambient PM_{2.5} levels are scarce. A pilot project along with a comprehensive atmospheric measurement campaign would be needed to assess the effectiveness of street sweeping as a method to reduce ambient PM_{2.5}.

BCM-15: EMISSION REDUCTIONS FROM ABRASIVE BLASTING OPERATIONS: This control measure seeks to reduce PM_{2.5} emissions from abrasive blasting operations. This control measure proposes voluntary applications of a portable blasting enclosure/booth with a dust collection system by providing incentives, primarily focusing on dry abrasive blasting operations conducted in open areas using portable blasting equipment with or without a South Coast AQMD permit.

BCM-16: EMISSION REDUCTIONS FROM STONE GRINDING, CUTTING AND POLISHING OPERATIONS: South Coast AQMD Rule 401 – Visible Emissions, prohibits from discharging of air contaminant that exceeds Ringelmann Chart No. 1 (equivalent to a 20 percent opacity) and Rule 403 – Fugitive Dust, prohibits fugitive dust emissions from any onsite mechanical activities such as cutting from being visible beyond the property line of the emission source. Various control measures to reduce the fugitive emissions are required as well. Rule 403 also prohibits the dust emissions from exceeding a 20 percent opacity limit, if dust emissions are the result of movement of a motorized vehicle. This control measure seeks to reduce PM emissions from stone grinding, cutting and polishing operations which are not regulated in Rule 401 or Rule 403. Moreover, Rule 219 – Equipment Not Requiring a Written Permit Pursuant to Regulation II, does not require permits for machining equipment exclusively used for polishing, cutting, surface grinding, etc. Both dry and wet dust control options are available to reduce dust emissions from such operations. Wet systems involve spraying water onto the rotating cutting disc to reduce dust emissions. Dry cutting emissions can be controlled at the point of operation using a portable dust collector, air scrubber and negative air machine to prevent dust from being released into the atmosphere. Financial incentives will be considered to exchange existing dry/wet equipment with new equipment that includes integrated add-on controls.

BCM-17: EMISSION REDUCTIONS FROM PRESCRIBED BURNING FOR WILDFIRE PREVENTION: This control measure, based on 2022 AQMP control measure MCS-02, seeks particulate matter emission reductions and property defensible space enhancements from fuel reduction efforts via hand-thinning, mechanical thinning, and the use of chipping equipment (chipping) to mitigate excess fuels at properties located in the residential urban-wild-interface (UWI) areas of the San Bernardino National Forest (SBNF). The proposed method of control is to coordinate with other agencies to provide funding for chipping operations for the remaining untreated area in the Mountain Rim Fire Safe Council's UWI. With the chipping program in place, homeowners in the UWI are much more compliant and engaged with assisting with fuel load reduction by trimming and removing excess hazardous vegetation, such as dead trees and leaf litter, for chipping than without the program.

BCM-18: FURTHER EMISSION REDUCTIONS FROM WOOD-BURNING FIREPLACES AND WOOD STOVES: This control measure seeks additional emission reductions from residential wood burning activities. Staff analysis determined that the wood burning curtailment program in Rule 445 is potentially less stringent compared to similar programs in other districts. In order to satisfy U.S. EPA's stringency requirements, this control measure proposes to lower the curtailment threshold from 29 µg/m³ to 25 µg/m³ retain the sole source of heat exemption and remove the low-income exemption in Rule 445. South Coast AQMD may also consider lowering the Basin-wide curtailment threshold if future analyses demonstrate that this would be needed to maintain the stringency of Rule 445. The sole source of heat exemption in Rule 445 would be retained.

BCM-19: EMISSION REDUCTIONS FROM UNPAVED ROAD DUST SOURCES: This control measure seeks to evaluate the potential to reduce PM_{2.5} emissions from well-traveled unpaved lots, roads, shoulders, and other surfaces by applying paving materials. There are approximately 1,900 miles of unpaved roads in the Basin. However, not all of these roads are well-traveled or highly used and therefore, the suitability for paving will be determined on a case-by-case basis. Vehicle miles traveled, proximity to AB 617 communities, whether the road exists in natural or protected lands, and the effects of paving on climate-related drought conditions and heatwaves will be taken into account in determining the suitability for paving.

South Coast AQMD Stationary Source Other Measures

There is one proposed measure in this category, BCM-20: Application of All Feasible Measures.

BCM-20: APPLICATION OF ALL FEASIBLE MEASURES: This control measure, based on 2022 AQMP control measure MCS-01, seeks to explore all feasible measures that achieve criteria pollutant reductions. Existing rules and regulations reflect current Best Available Retrofit Control Technology (BARCT). However, BARCT continually evolves as new technology becomes available that is feasible and cost-effective. South Coast AQMD staff would continue to review new emission limits or controls introduced through federal, State or local regulations to determine if South Coast AQMD regulations remain equivalent or more stringent than rules in other regions. If not, a rulemaking process will be initiated to perform a BARCT analysis and potential rule amendments if deemed feasible. In addition, the South Coast AQMD will consider adopting and implementing new retrofit technology control standards, based on research and development and other information, that are feasible and cost-effective.

South Coast AQMD Proposed Mobile Source Measures

While the bulk of the authority to regulate mobile sources rests with CARB and the federal government, the South Coast AQMD also has a role in achieving emission reductions from these sources. The proposed South Coast AQMD mobile source measures are based on a variety of control technologies that are commercially available and/or technologically feasible to implement prior to the attainment year of 2030. The focus of these measures includes accelerated retrofits or replacement of existing vehicles or equipment, acceleration of vehicle turnover through voluntary vehicle retirement programs, and greater use of cleaner fuels in the near-term. The measures will encourage greater deployment of low NO_x and zero emission vehicle and equipment technologies such as plug-in hybrids, battery-electric, and fuel cells to the maximum extent feasible as such technologies are commercialized and become available.

The South Coast AQMD proposes a total of 15 mobile source measures which are categorized into five groups – emission growth management, facility-based mobile sources, on-road and off-road, incentives, and other (see Table 4-3). Two emission growth management measures (EGM-01 and EGM-02) are proposed to identify actions to help mitigate and potentially provide emission reductions due to new development and redevelopment projects. Four facility-based mobile source measures (FBMSMs) (MOB-01 to MOB-04) seek to identify actions that will result in additional emission reductions at commercial

marine ports, rail yards, warehouse distribution centers, and commercial airports. FBMSMs for marine ports and rail yards are currently undergoing a process to develop Indirect Source Rules. Six on-road and off-road mobile measures focus on on-road light/medium/heavy-duty vehicles, international shipping vessels, passenger locomotives and small off-road engines. Additionally, incentive-based measures such as MOB-11 will use established protocols such as Carl Moyer Program guidelines and report to the Governing Board periodically. MOB-12, Pacific Rim Initiative for Maritime Emission Reductions (PRIMER) seeks NOx emission reductions from partnership with local, State, federal and international entities. One other measure (MOB-13) focuses on fleet vehicle mitigation options and the development of a work plan to support and accelerate the deployment of zero emission infrastructure needed for the widespread adoption of zero emission vehicles and equipment that is described in more detail in Appendix IV-A.

TABLE 4-3
SOUTH COAST AQMD PROPOSED MOBILE SOURCE MEASURES

Number	Title [Pollutant]	Previous Plan Measure Was Included	Emission Reductions by 2030 (tons per day)
South Coast AQMD Emission Growth Management Measures:			
EGM-01	Emission Reductions from New Development and Redevelopment [All Pollutants]	2022 AQMP (EGM-01)	TBD
EGM-02	Emission Reductions from Clean Construction Policy [All Pollutants]	2022 AQMP (EGM-03)	TBD
South Coast AQMD Facility-Based Measures:			
MOB-01	Emission Reductions at Commercial Marine Ports [NOx, PM]	2022 AQMP (MOB-01)	TBD
MOB-02	Emission Reductions at New and Existing Rail Yards [NOx, PM]	2022 AQMP (MOB-02A & B)	TBD
MOB-03	Emission Reductions at Warehouse Distribution Centers [NOx, PM2.5]	2022 AQMP (MOB-03)	TBD
MOB-04	Emission Reductions at Commercial Airports	2022 AQMP (MOB-04)	TBD
South Coast AQMD On-Road and Off-Road Measures:			
MOB-05	Accelerated Retirement of Light-Duty and Medium-Duty Vehicles [NOx, PM]	2022 AQMP (MOB-05)	TBD
MOB-06	Accelerated Retirement of On-Road Heavy-Duty Vehicles [NOx, PM]	2022 AQMP (MOB-06)	TBD

Number	Title [Pollutant]	Previous Plan Measure Was Included	Emission Reductions by 2030 (tons per day)
MOB-07	On-Road Mobile Source Emission Reduction Credit Generation Program [NOx, PM]	2022 AQMP (MOB-07)	TBD
MOB-08	Small Off-Road Engine Equipment Exchange Program [VOCs, NOx, PM]	2022 AQMP (MOB-08)	TBD
MOB-09	Further Emission Reductions from Passenger Locomotives [NOx, PM]	2022 AQMP (MOB-09)	TBD

South Coast AQMD Incentive-Based Measures:			
MOB-11	Emission Reductions from Incentive Programs [NOx, PM]	2022 AQMP (MOB-11)	TBD
MOB-12	Pacific Rim Initiative for Maritime Emission Reductions [NOx, PM]	2022 AQMP (MOB-12)	TBD
South Coast AQMD Other Mobile Source Measures:			
MOB-13	Rule 2202 – On-Road Motor Vehicle Mitigation Options [NOx, PM2.5]	2022 AQMP (MOB-14)	TBD

South Coast AQMD Mobile Source Emission Growth Management Measures

There are two proposed control measures within this category:

- EGM-01: Emission Growth Management from New Development and Redevelopment
- EGM-02: Emission Reductions from Clean Construction Policy

EGM-01: EMISSION GROWTH MANAGEMENT FROM NEW DEVELOPMENT AND REDEVELOPMENT: The goal of this measure is to identify emission reduction opportunities and to mitigate and, where appropriate, reduce emissions from new development or redevelopment projects such as residential, commercial, and industrial projects that are otherwise not included in other FBMSMs identified in the 2022 AQMP. This proposed control measure, based on 2022 AQMP control measure EGM-01, seeks PM2.5 co-benefit emission reductions primarily from project construction activities by increasing the deployment of zero emission and low NOx emission technologies for on-road and off-road mobile sources. South Coast AQMD staff has held three Working Group meetings for the development of EGM-01. South

Coast AQMD staff will continue soliciting stakeholders' input towards the development of a method of control for EGM-01. Emission reductions and their SIP creditability will be determined dependent on the final method of control to be implemented.

EGM-02: EMISSION REDUCTIONS FROM CLEAN CONSTRUCTION POLICY: The purpose of this control measure is to identify potential approaches to mitigate and control emissions from construction activities in the South Coast Air Basin. This control measure, based on 2022 AQMP control measure EGM-03, will seek to develop a Clean Construction Policy (CCP) which can be utilized for reference and voluntary implementation by local municipalities and public agencies. The South Coast AQMD will work in collaboration with local municipalities, construction industry, and other affected stakeholders to develop such a policy and will consider existing control measures and best management practices that are currently being implemented by entities throughout California.

South Coast AQMD Facility-Based Measures

FBMSMs are derived from the 2022 AQMP and are included in the PM2.5 Plan for the purpose of evaluating whether their implementation can be accelerated. FBMSMs are aimed at reducing the emissions from indirect sources – facilities that do not emit much air pollution directly, but instead attract mobile sources which contribute significant emissions. There are four proposed control measures within this category:

- MOB-01: Emission Reductions at Commercial Marine Ports
- MOB-02: Emission Reductions at New and Existing Rail Yards
- MOB-03: Emission Reductions at Warehouse Distribution Centers
- MOB-04: Emission Reductions at Commercial Airports

MOB-01: EMISSION REDUCTIONS AT COMMERCIAL MARINE PORTS: This measure seeks to reduce NO_x, VOC, and PM emissions related to on-road heavy-duty vehicles, ocean going vessels, cargo handling equipment, locomotives, and harbor craft that go to and from the Ports of Los Angeles and Long Beach (Ports). As a follow up to implementation of MOB-01 from the 2016 AQMP, the South Coast AQMD is working on a variety of measures, including Proposed Rule 2304, to address emissions from marine ports. Through a public process, rule concepts and other measures will be proposed to address emissions from these sources. Rule development will continue to focus on deploying the cleanest technologies possible and supporting zero emissions fueling charging infrastructure as quickly as feasible. Incentive funding that supports the transition to cleaner technologies will also continue to be pursued to assist in implementing this measure.

MOB-02: EMISSION REDUCTIONS AT NEW AND EXISTING RAIL YARDS: This measure seeks to reduce NO_x and PM emissions related to on-road heavy-duty vehicles, off-road equipment, and locomotives at new and existing rail yards. Through a public process, the South Coast AQMD will assess and identify potential

actions that could result in further emission reductions at new facilities. This measure may include voluntary measures as well as additional actions which could include development of a rule as well as pursuit of incentive funding that can achieve and/or facilitate additional emission reductions. Emission reductions may also be achieved if new regulations are developed and implemented at the state or federal level.

MOB-03: EMISSION REDUCTIONS AT WAREHOUSE DISTRIBUTION CENTERS: The goal of this measure to reduce NO_x and PM emissions related to mobile sources and other equipment associated with warehouses. The strategy utilizes a menu-based point system in Rule 2305 (adopted in May 2021) to implement MOB-03 from the 2016 AQMP, where warehouses subject to the rule must annually earn points based on the amount of truck traffic at their facility. The menu includes actions that warehouse operators can take to reduce emissions, or to facilitate emission reductions from their operations. Required actions result in emission reductions when compared to conventional diesel technology, assist in implementation of other related measures, promote the demand for zero emission and low NO_x technology, foster early action of compliance, and infrastructure installation to support new or emerging zero emission technologies. Implementation of this measure will include ensuring that applicable warehouses comply with Rule 2305, quantifying the air quality benefits of Rule 2305 as they occur and seeking to incorporate those benefits as SIP-creditable emission reductions, evaluating the state of technology every five years and recommending if Rule 2305 should potentially be amended.

MOB-04: EMISSION REDUCTIONS AT COMMERCIAL AIRPORTS: The Facility-Based Mobile Source Measure for Commercial Airports, which controls non-aircraft mobile sources at commercial airports, was adopted by the South Coast AQMD on December 6, 2019. The measure consists of Memoranda of Understanding (MOUs) between the South Coast AQMD and five commercial airports in the Basin to develop and implement air quality improvement plans. The MOUs were executed with Los Angeles International Airport, John Wayne Orange County Airport, Hollywood Burbank Airport, Ontario International Airport, and Long Beach Airport. Each MOU contains performance targets for cleaner ground support equipment, airport shuttle buses, and heavy-duty trucks. Based on the measures in the MOUs, the South Coast AQMD committed to achieve 0.52 and 0.37 tons per day NO_x reductions in 2023 and 2031, respectively. Implementation of this measure will include ensuring that applicable airports comply with the performance targets in the MOUs. South Coast AQMD will encourage airports to accelerate implementation of the MOU measures ahead of 2031 so that emission reductions in 2030 can be quantified.

South Coast AQMD On-Road and Off-Road Measures

A total of six on-road and off-road mobile source measures derived from the 2022 AQMP are proposed to be included in the PM_{2.5} Plan as listed below.

- MOB-05: Accelerated Retirement of Light-Duty and Medium-Duty Vehicles
- MOB-06: Accelerated Retirement of On-Road Heavy-Duty Vehicles
- MOB-07: On-Road Mobile Source Emission Reduction Credit Generation Program
- MOB-08: Small Off-Road Engine Equipment Exchange Program
- MOB-09: Further Emission Reductions from Passenger Locomotives
- MOB-10: Off-Road Mobile Source Emission Reduction Credit Generation Program

MOB-05: ACCELERATED RETIREMENT OF LIGHT-DUTY AND MEDIUM-DUTY VEHICLES: The purpose of this control measure is to achieve emission reductions by accelerating retirement of older gasoline- and diesel-powered vehicles with up to 8,500 lbs. gross vehicle weight rating (GVWR). These vehicles include passenger cars, sports utility vehicles, vans, and light-duty pick-up trucks. The South Coast AQMD has been implementing the Replace Your Ride (RYR) Program since 2015 which provides a rebate to low- and moderate-income applicants for replacing their existing cars with newer, cleaner conventionally powered vehicles, plug-in hybrid electric vehicles or dedicated zero emission vehicles. This measure seeks to retire up to 2,000 light- and medium-duty vehicles annually through continued implementation of the RYR Program with incentives up to \$12,000 for residents in a Disadvantaged Community (DAC) zip code. For plug-in hybrid and battery electric vehicles, an additional incentive of up to \$2,000 is also provided for the installation of electric vehicle charging equipment.

MOB-06: ACCELERATED RETIREMENT OF ON-ROAD HEAVY-DUTY VEHICLES: This proposed control measure seeks additional emission reductions from existing heavy-duty vehicles with GVWR greater than 8,500 lbs through an accelerated vehicle replacement program with zero or low NO_x emission vehicles. One of the options being considered is a plus-up program to leverage existing incentive programs such as Carl Moyer and Prop 1B or other grant funding opportunities by providing supplemental funding to help truck owners and fleets with the purchase of cleaner engine vehicles, including zero emission trucks. This type of program would be especially helpful for individual operators and owners with limited financial resources to purchase or lease zero emission trucks which are still relatively costly compared to conventional vehicles.

MOB-07: ON-ROAD MOBILE SOURCE EMISSION REDUCTION CREDIT GENERATION PROGRAM: This proposed measure seeks to develop mechanisms to incentivize the early deployment of low NO_x and zero emission on-road heavy-duty trucks through the generation of mobile source emission reduction credits (MSERCs) which can be used as an alternative means of compliance with certain South Coast AQMD

regulations. These MSERCs will be used only by entities affected by the 2022 AQMP control measures MOB-01 through MOB-04, EGM-01, and EGM-03. South Coast AQMD staff will develop amendments to South Coast AQMD Rules 1612 and/or 1612.1 to provide greater flexibility, such as expanding the eligibility of vehicle types and projects as well as providing more flexibility in the application and use of MSERCs, for accelerated deployment of low NOx and zero emission heavy-duty vehicles in the Basin and Coachella Valley.

MOB-08: SMALL OFF-ROAD ENGINE EQUIPMENT EXCHANGE PROGRAM: This measure seeks to reduce NOx emissions by promoting the accelerated turn-over of in-use small off-road engines and other engines, such as those used in larger diesel-powered lawn and garden equipment, through expanded voluntary exchange programs. Since 2003, the South Coast AQMD has sponsored a lawn mower exchange programs for residential users of old lawn mowers which is now known as the Electric Lawn Mower Rebate Program. Since its inception, this program has replaced approximately 59,000 high polluting gasoline-powered lawn mowers with electric lawn mowers. The South Coast AQMD also launched the Commercial Electric Lawn and Garden Equipment Incentive and Exchange Program (Commercial L&G Equipment Program) in 2018 to accelerate the replacement of old gasoline- or diesel-powered commercial lawn and garden equipment with zero emission, battery electric technology. This program provides a point-of-sale discount of up to 75 percent off the purchase price of a variety of new electric equipment including lawn mowers (ride-on, stand-on and walk-behind mowers), handheld trimmers, chainsaws, and pruners in addition to backpack and handheld leaf blowers. More recently, the South Coast AQMD has also started a new battery rebate program for commercial lawn and garden equipment that funds up to 75 percent of the rechargeable battery cost with a maximum limit of three batteries per equipment. Moving forward, the South Coast AQMD will increase the number of outreach and exchange events as well as continue to seek additional funding opportunities and resources to expand the scope and types of equipment and engines that can be funded by these programs.

MOB-09: FURTHER EMISSION REDUCTIONS FROM PASSENGER LOCOMOTIVES: This measure seeks to promote earlier and cleaner replacement or upgrade of existing passenger locomotives with Tier 4 or cleaner locomotives. The South Coast AQMD is continuing to work collaboratively with other stakeholders to explore the feasibility of zero and low NOx emission locomotive technologies such as battery electric or fuel cell engine-driven systems. For example, the South Coast AQMD has been actively participating in the development and demonstration of zero emission battery-operated switcher locomotives in CARB-funded projects in the San Pedro Bay Ports since 2018. Through this measure, the South Coast AQMD will continue to not only promote earlier replacement or upgrade of existing passenger trains with Tier 4 locomotives, but also support the development and adoption of zero or low NOx emission technologies.

MOB-10: OFF-ROAD MOBILE SOURCE EMISSION REDUCTION CREDIT GENERATION PROGRAM: This measure seeks to develop mechanisms to incentivize the early deployment of Tier 4, low NOx, and zero off-road mobile combustion equipment, where applicable, through the generation of MSERCs. These MSERCs will be used only by entities affected by the 2022 AQMP control measures MOB-01 through MOB-04, EGM-01, and EGM-02; and cannot be used to offset emissions from stationary sources. These MSERCs will be discounted to provide additional emission reductions to help meet air quality standards. South

Coast AQMD staff seeks to amend Rule 1620 to provide greater flexibility for entities to initiate projects to accelerate the deployment of zero and low NOx emission off-road mobile equipment in the South Coast Air Basin and Coachella Valley.

South Coast AQMD Incentive-Based Measures

Two incentive-based mobile source measures are also included:

- MOB-11: Emission Reductions from Incentive Programs
- MOB-12: Pacific Rim Initiative for Maritime Emission Reductions

MOB-11: EMISSION REDUCTIONS FROM INCENTIVE PROGRAMS: This control measure seeks to apply the administrative mechanism, as initially proposed in the 2016 AQMP and revisited in the 2022 AQMP, to quantify and take credit for the emission reductions achieved through the implementation of South Coast AQMD-administered incentive programs for SIP purposes. The South Coast AQMD has been implementing a variety of incentive programs including, but not limited to, Carl Moyer Memorial Air Quality Standards Attainment Program, Proposition 1B, Lower Emission School Bus, Community Air Protection Program, and Volkswagen Environmental Mitigation Trust. Examples of projects funded by these programs include heavy-duty vehicle/equipment replacements, installation of retrofit units, and engine repowers. The emission reductions from these incentive programs will be calculated in two parts. First, the actual emission reductions associated with existing projects that were funded by 2021 with the remaining project life through 2030 are quantified. Second, potential reductions that are projected from the implementation of future projects to be funded through these incentive programs are quantified. These reductions will be estimated based on the projected level of funding for the programs and average emission reductions achieved by past projects, discounted by control factors for future years.

MOB-12: PACIFIC RIM INITIATIVE FOR MARITIME EMISSION REDUCTIONS: This measure, initially developed in the 2022 AQMP, seeks to reduce emissions from OGV through an incentive-based program to encourage the deployment of cleaner OGV to the Ports. This approach includes collaborating with international port authorities and shipping lines to establish common goals to reduce criteria pollutants from OGV. Incentives could be monetary (e.g., a per-visit payment for cleaner ships) or non-monetary (e.g., preferred berthing for cleaner ships). The cleanest commercially available OGV currently meet Tier III emission standards, however this class of vessels is not expected to be widely deployed for many years, in part due to the high cost of constructing new vessels and the difficulty in retrofitting existing vessels to Tier III standards. This measure would quicken the return on investment for these cleaner vessels by ensuring that shipping lines receive a benefit for every clean ship visit to a port with an incentive program. Clean ships could include Tier III vessels, retrofitted vessels that surpass Tier II standards, and eventually zero emissions shipping when it becomes available.

South Coast AQMD Other Mobile Source Measures

There is one proposed other mobile source measure, MOB-13: Rule 2202 – On-Road Motor Vehicle Mitigation Options, which is based on 2022 AQMP control measure MOB-14.

MOB-13: RULE 2202 – ON-ROAD MOTOR VEHICLE MITIGATION OPTIONS: This control measure proposes to reduce emissions by evaluating potential amendments to Rule 2202. Rule 2202 has been developed to reduce emissions associated with work commute trips. Specifically, larger employers in the region with more than 250 employees are required to mitigate employee commute trips into the worksite. Rule 2202 provides employers with a menu of options to select from to implement a combination of emission reduction strategies to meet an emission reduction target (ERT) for their worksite. During the Coronavirus (COVID-19) pandemic in 2020 and 2021, many Rule 2202 regulated employers (where applicable) incorporated widespread telecommuting practices which further reduced emissions by reducing commute trips into the worksite. Based on conditions observed and reported during the time-period, Rule 2202 was amended on August 4, 2023. The amended Rule 2202 includes two phases. The first phase (adopted August 4, 2023) focused on data collection and reporting that will be used to inform a potential second phase of rulemaking. Specifically, the first phase requires new limited reporting for all regulated worksites, including the reporting of telecommute activity, VMT data, and business type/classification for all worksites. The second phase will consider using VMT as an option to evaluate travel patterns, re-assess rule targets, explore multiple compliance options for zero emission vehicles and infrastructure, evaluate options to continue the use of credit, and consider modifying rideshare options. The new option will include placing a larger focus on telecommuting strategies.

Summary of South Coast AQMD Control Strategy

The PM2.5 Plan primarily requires NO_x emission reductions to meet the 2012 annual PM2.5 standard. The pathway to achieving the standard involves accelerated implementation of the 2022 AQMP and 2022 State SIP Strategy, with a limited control strategy for NH₃ and direct PM2.5 sources.

The control strategies in the PM2.5 Plan include both regulations and incentive programs. The control strategy is described in greater detail in Appendix IV-A. Tables 4-4 and 4-5 list emission reductions by 2030 and proposed adoption/implementation dates of the stationary source control measures and mobile source control measures, respectively. South Coast AQMD will develop, adopt, submit, and implement the control measures in Tables 4-4 and 4-5 as expeditiously as possible in order to meet or exceed the commitments needed to attain the 2012 annual PM2.5 standard, and to substitute any other measures as necessary to make up any emission reduction shortfall.

**TABLE 4-4
EMISSION REDUCTIONS AND ADOPTION AND IMPLEMENTATION SCHEDULE OF STATIONARY
SOURCE CONTROL MEASURES**

Number	Title [Pollutant]	Emission Reductions by 2030 (tons per day)	Proposed Adoption Date	Proposed Implementation Timeframe
South Coast AQMD NOx Measures:				
BCM-01	Emission Reductions from Replacement with Zero Emission or Low NOx Appliances – Residential Water Heating [PM2.5, NOx]	TBD	2024	2029
BCM-02	Emission Reductions from Replacement with Zero Emission or Low NOx Appliances – Residential Space Heating [PM2.5, NOx]	TBD	2024	2029
BCM-03	Emission Reductions from Residential Cooking Devices [PM2.5, NOx]	TBD	2027	2029
BCM-04	Emission Reductions from Replacement with Zero Emission or Low NOx Appliances – Residential Other Combustion Sources [PM2.5, NOx]	TBD	2027	2029
BCM-05	Emission Reductions from Emergency Standby Engines [PM2.5, NOx]	0.04 [PM2.5] 0.36 [NOx]	2025	2030
BCM-06	Emission Reductions from Diesel Electricity Generating Facilities [NOx]	0.16	2027	2030
BCM-07	Emission Reductions from Incinerators [NOx]	0.81	2024	2029
South Coast AQMD Co-Benefits from Energy and Climate Change Programs Measures:				
ECC-01	Co-benefits from Existing and Future Greenhouse Gas Programs, Policies, and Incentives [PM2.5, NOx]	TBD	N/A	N/A
ECC-02	Co-benefits from Existing and Future Residential and Commercial Building Energy Efficiency Measures [PM2.5, NOx]	TBD	N/A	N/A

Number	Title [Pollutant]	Emission Reductions by 2030 (tons per day)	Proposed Adoption Date	Proposed Implementation Timeframe
ECC-03	Additional Enhancements in Reducing Existing Residential Building Energy Use [PM2.5, NOx]	TBD	N/A	N/A
South Coast AQMD NH3 Measures:				
BCM-08	Emission Reductions from Livestock Waste at Confined Animal Facilities* [NH3]	TBD <u>0.27</u>	2025	2030
BCM-09	Ammonia Emission Reductions from NOx Controls [NH3]	TBD	N/A	N/A
BCM-10	Emission Reductions from Direct Land Application of Chipped and Ground Uncomposted Greenwaste* [NH3]	TBD <u>0.08</u>	2026	2030
BCM-11	Emission Reductions from Organic Waste Composting [NH3]	TBD	N/A	N/A
South Coast AQMD Direct PM2.5 Measures:				
BCM-12	Further Emission Reductions from Commercial Cooking* [PM2.5]	TBD	2027	2030
BCM-13	Emission Reductions from Cooling Towers [PM2.5]	TBD	N/A	N/A
BCM-14	Further Emission Reductions from Paved Road Dust Sources [PM2.5]	TBD	N/A	N/A
BCM-15	Emission Reductions from Abrasive Blasting Operations [PM2.5]	TBD	N/A	N/A
BCM-16	Emission Reductions from Stone Grinding, Cutting and Polishing Operations [PM2.5]	TBD	N/A	N/A
BCM-17	Emission Reductions from Prescribed Burning for Wildfire Prevention [PM2.5, NOx]	TBD	N/A	N/A
BCM-18	Further Emission Reductions from Wood-Burning Fireplaces and Wood Stoves* [PM2.5]	TBD <u>0.33</u>	2026	2030

Number	Title [Pollutant]	Emission Reductions by 2030 (tons per day)	Proposed Adoption Date	Proposed Implementation Timeframe
BCM-19	Emission Reductions from Unpaved Road Dust Sources [PM _{2.5}]	TBD	N/A	N/A
South Coast AQMD Other Measures:				
BCM-20	Application of All Feasible Measures [PM _{2.5} , NO _x]	TBD	N/A	N/A

* These measures are included to satisfy MSM requirements.

Proposed CARB Commitment for the South Coast

Overview of Commitment

SIPs may contain enforceable commitments to achieve the level of emissions necessary to meet federal air quality standards, as defined by the attainment demonstration. CARB's 2022 State Strategy for the State Implementation Plan¹ (2022 State SIP Strategy) lists new SIP measures for which potential emissions reduction SIP commitments for the South Coast in 2030 are now estimated based on the measures identified and quantified to date. Adoption of the 2022 State SIP Strategy and the measure schedule by the CARB Board on September 22, 2022, formed the basis of the commitments for emission reductions by the 2030 attainment deadline for South Coast that will be proposed for CARB Board consideration alongside the 2024 South Coast PM2.5 SIP. The commitments consist of two components:

¹ https://ww2.arb.ca.gov/sites/default/files/2022-08/2022_State_SIP_Strategy.pdf

1. A commitment to bring an item to the CARB Board for defined new measures or take other specified actions within CARB's authority; and
2. A commitment to achieve aggregate emission reductions by specific dates.

As part of each SIP needing emission reductions from the State, the total aggregate emission reductions and the obligation to make certain proposals to the CARB Board or take other actions within CARB's authority specified in the 2022 State SIP Strategy would become enforceable upon approval by U.S. EPA. While the 2022 State SIP Strategy discusses a range of measures and actions, those measures and actions are still subject to CARB's formal approval process and would not be final until the CARB Board takes action.

Commitment to Act on Measures

For each of the SIP measures shown in Table 4-6, CARB committed in the 2022 State SIP Strategy to address each measure as described. For each measure committed to, CARB staff would undertake the actions detailed for each measure. In the instance of measures that involve the development of a rule under CARB's regulatory authority, CARB committed to bring a publicly noticed item before the CARB Board that is either a proposed rule, or is a recommendation that the CARB Board direct staff to not pursue a rule covering that subject matter at that time. This recommendation would be based on an explanation of why such a rule is unlikely to achieve the relevant emission reductions in the relevant timeframe, and would include a demonstration that the overall aggregate commitment will be achieved despite that rule not being pursued. This public process and CARB hearing would provide additional opportunity for public and stakeholder input, as well as ongoing technology review, and assessments of costs and environmental impacts.

The measures, as proposed by staff to the CARB Board or adopted by the CARB Board, may provide more or less than the initial emission reduction estimates. In addition, action by the CARB Board may include any action within its discretion.

TABLE 4-6
2022 STATE SIP STRATEGY MEASURES AND SCHEDULE

Measure	Agency	Action	Implementation Begins
On-Road Heavy-Duty			
Advanced Clean Fleets Regulation	CARB	2023	2024
Zero-Emissions Trucks Measure	CARB	2028	2030
On-Road Light-Duty			
Clean Miles Standard	CARB	2021	2023
Off-Road Equipment			
Tier 5 Off-Road Vehicles and Equipment	CARB	2025	2029
Amendments to the In-Use Off-Road Diesel-Fueled Fleets Regulation	CARB	2022	2024
Transport Refrigeration Unit Regulation Part 2	CARB	2026	2028
Commercial Harbor Craft Amendments	CARB	2022	2023
Cargo Handling Equipment Amendments	CARB	2027	2030
Other			
Zero-Emission Standard for Space and Water Heaters	CARB	2025	2030
Primarily-Federally and Internationally Regulated Sources – CARB Measures			
In-Use Locomotive Regulation	CARB	2023	2024

Commitment to Achieve Emission Reductions

The following section describes the estimated emission reduction and potential commitment from the SIP measures identified and quantified to date for the South Coast. The aggregate commitment of emissions reductions from State sources to be proposed for CARB Board consideration will be found in CARB's staff report for the 2024 South Coast PM2.5 SIP when it is brought to the CARB Board and is summarized below.

While CARB includes estimates of the emission reductions in 2030 from each of the individual new measures, CARB's overall commitment is to achieve the total emission reductions necessary from State-regulated sources to attain the federal air quality standards, reflecting the combined reductions from the existing control strategy and new measures. Therefore, if a particular measure does not get its expected emission reductions, the State's overall commitment to achieving the total aggregate emission reductions still exists. If actual emission decreases occur that exceed the projections reflected in the current emission

inventory, CARB will submit an updated emissions inventory to U.S. EPA as part of a SIP revision. The SIP revision would outline the changes that have occurred and provide appropriate tracking to demonstrate that aggregate emission reductions sufficient for attainment are being achieved through enforceable emission reduction measures. CARB's emission reduction commitments may be achieved through a combination of actions including but not limited to the implementation of control measures; the expenditure of local, State or federal incentive funds; or through other enforceable measures.

Emission Reductions

CARB's control programs, including the measures in the 2022 State SIP Strategy provide emission reduction benefits throughout the State. Although the existing control program will provide mobile source emission reductions necessary to meet the attainment needs of many areas of the State, the new measures in the 2022 State SIP Strategy are needed to provide further reductions to achieve the 12 $\mu\text{g}/\text{m}^3$ PM_{2.5} annual standard in the South Coast and enhance statewide air quality progress towards the 9 $\mu\text{g}/\text{m}^3$ annual PM_{2.5} standard promulgated in 2024.

Emission Reductions from Current Programs

Table 4-7 provides the mobile source emissions under CARB and district current programs for the South Coast. Ongoing implementation of current control programs is projected to reduce mobile source emissions of direct PM_{2.5} and NO_x by 3.3 tpd and 160.6 tpd in the South Coast in 2030 compared to 2018 levels, respectively. Although the current mobile source baseline shows an increase in ammonia (NH₃) emissions in 2030 compared to 2018 levels, this baseline does not reflect emissions reductions from a number of recently-adopted CARB regulations identified in Table 4-5. When taking these reductions taken into account, NH₃ emissions are projected to only increase by 1.8 tpd in 2030 compared to 2018 levels. Achieving the benefits projected from the current control program will continue to require significant efforts for implementation and enforcement and thus represents an important element of the overall strategy.

TABLE 4-7
SOUTH COAST BASELINE MOBILE SOURCE EMISSIONS²

Pollutant	2018 Emissions (tpd)	2030 Emissions (tpd)	Change
PM _{2.5}	10.8	7.4	-31%
NO _x	323.3	162.6	-50%
NH ₃	16.5	21.3	29%

² Source: MSC_NAA_CEPAM_v101B; does not reflect emissions reductions from recently-adopted CARB regulations identified in Table 5

Although most of the 2016 State SIP Strategy measure commitments have been adopted, there remains the Zero-Emission Forklift measure which will be acted upon by the CARB Board in 2024. Table 4-8 below shows the timeline and anticipated emission reductions for this measure.

TABLE 4-8
SOUTH COAST REDUCTIONS FROM REMAINING 2016 STATE SIP STRATEGY MEASURE³

Measure	Action	Implementation Begins	2030 NOx (tpd)	2030 PM2.5 (tpd)	2030 NH3 (tpd)
Zero-Emission Forklift	2024	2026	0.8	<0.1	NYQ*

* Not yet quantified.

Emission Reductions from 2022 State SIP Strategy Measures

In addition to controlling direct PM2.5, air quality modeling has determined that NOx and ammonia are significant precursors for the 12 µg/m³ annual PM2.5 standard in the South Coast, and that ammonium nitrate contributes 20 to 35 percent of total PM2.5 in the region, varying by season and location. Further, modeling indicates that total NOx emissions from all sources in the South Coast will need to decrease by approximately 55 percent from 2018 levels in order to attain the 12 µg/m³ annual PM2.5 standard in 2030. A significant fraction of the needed reductions will come from the existing control program already in the baseline emission inventory. In addition, as described above, one measure commitment included in the 2016 State SIP Strategy has not yet been acted upon, and a number of measure commitments included in both the 2016 and 2022 State SIP Strategies were very recently adopted and are thus not yet in the baseline emissions inventory, as outlined in Table 4-8 above and Table 4-9 below.

The measures contained in the 2022 State SIP Strategy commitment reflect a variety of State actions across on-road and off-road vehicle and appliance sectors. Collectively, emissions reductions from CARB's current control program, reductions from the 2016 and 2022 State SIP Strategy measures adopted but not yet in the baseline, reductions from the remaining 2016 State SIP Strategy measure, and reductions estimated from the future measures identified in the 2022 State SIP Strategy and quantified below will provide the reductions needed from State sources to support attainment of the 12 µg/m³ annual PM2.5 standard in the South Coast. Table 4-9, 4-10, and 4-11 summarize the reductions from the identified and quantified measures. In Table 4-9, the reductions estimated from the remaining 2016 State SIP Strategy measure and future measures identified in the 2022 State SIP Strategy are described as the "potential CARB aggregate emissions reductions commitment" until staff proposes and the CARB Board adopts the aggregate emissions reductions commitment for the year 2030. The reductions in Table 4-9 are needed

³ Numbers may not add up due to rounding

to demonstrate reasonable further progress (RFP) towards attainment. More details can be found in Chapter 6 of this Plan.

TABLE 4-9
2030 SOUTH COAST EMISSIONS REDUCTIONS FROM CARB PROGRAMS⁴

CARB Programs in South Coast	NO _x (tpd)	PM _{2.5} (tpd)	NH ₃ (tpd)
Current Control Program ⁵	172.8	1.9	-4.7 ⁶
2016 and 2022 State SIP Strategy Measures Adopted (Not yet in baseline inventory)	20.5	0.8	2.9
Potential CARB Aggregate Emissions Reductions Commitment	9.1	0.5	0.2
2016 State SIP Strategy Measure Remaining	0.8	<0.1	NYQ*
2022 State SIP Strategy Measures Remaining	8.2	0.5	0.2
Total Reductions	202.4	3.2	-1.4

* Not yet quantified.

Table 4-10 reflects the 2016 and 2022 State SIP Strategy measure commitments that the CARB Board has recently adopted. The associated emissions reductions from these recently adopted measures are not yet all accounted for in the baseline emissions inventory. Nonetheless, CARB measure commitments are achieving emissions reductions and will contribute towards attainment of the 12 µg/m³ annual PM_{2.5} standard in South Coast in 2030.

⁴ Numbers may not add up due to rounding

⁵ Current Control Program represents the current baseline emissions out to 100 nautical miles with adopted CARB and district measures excluding those recently-adopted CARB regulations identified in Table 5 (Source: MSC_NAA_CEPAM_v101B)

⁶ Negative number indicates growth in emissions

Title VI of the Civil Rights Act of 1964

Title VI of the Civil Rights Act of 1964 (Title VI) provides that no person in the United States shall, on the basis of race, color, or national origin, be excluded from participation in, be denied the benefits of, or be subjected to discrimination under any program or activity receiving federal financial assistance. As a recipient of federal funds, CARB must ensure it complies with Title VI and U.S. EPA's Title VI implementation regulations in its relevant programs and policies. In developing the 2022 State SIP Strategy's robust suite of control measures, CARB staff engaged in a thorough public process that addresses the requirements of Title VI. CARB will continue to address the requirements of Title VI in

⁷ Numbers may not add up due to rounding

⁸ Reductions may be achieved through CARB and/or complementary South Coast AQMD control measures for this sector

implementation of the 2022 State SIP Strategy and related Clean Air Act implementation activities. Written guidance from U.S. EPA is needed to provide additional detail on Title VI requirements and expectations and support for effective implementation efforts.

Many low-income and disadvantaged communities in nonattainment areas, and across the State, continue to experience disproportionately high levels of air pollution and the resulting detrimental impacts to their health. Research shows large disparities in exposure to pollution between disadvantaged communities and other communities. There are disparities between white and non-white populations in California, with Black and Latino populations experiencing significantly greater air pollution impacts than white populations. Mobile source pollution exposures show some of the highest disparities. Mobile sources are the largest sources of pollution exposure disparity for Black populations and disadvantaged community residents, when compared to the average population in California. Specifically, mobile sources accounted for 45 percent of exposure disparity for the Black population, and 37 % of exposure disparity for people in disadvantaged communities. While significant progress has been made in reducing mobile and stationary source pollution in California through regulatory and other program activities, disparities in the location of pollution and cumulative exposures continue.

In 2023, CARB adopted the following Vision for Racial Equity to guide our external work, including the implementation of the Community Air Protection Program: CARB commits to just social change by working at all levels within the organization and externally to address environmental injustices and advance racial equity in the achievement of its mission. CARB works toward a future where all Californians breathe healthy and clean air, benefit from actions to address climate change, and where race is no longer a predictor of life outcomes. In working to realize this vision, CARB prioritizes environmental justice, uses tools to operationalize racial equity, and conducts meaningful community engagement in its policy and planning efforts and programs to address the longstanding environmental and health inequities from elevated levels of toxic air contaminants, criteria pollutants, and secondary impacts of climate change. It is imperative to optimize California's control programs to maximize emissions reductions and provide targeted near-term benefits in those communities that continue to bear the brunt of poor air quality. Specific efforts include a commitment to apply a racial equity lens in considering benefits and burdens of CARB's programs and policies, including regulatory actions. A racial equity lens is a set of questions to estimate impacts and benefits on the basis of race, ethnicity or other relevant categories, and considering alternatives.

Using a racial equity lens also requires a commitment to meaningful community engagement. In support of this commitment, CARB recently contracted with a number of community experts to vet and refine a model framework for community engagement. As noted above, while significant progress has been made to address air pollution statewide and in local communities, ensuring all Californians have access to healthy air quality is imperative.

In addition to these important efforts, the 2022 State SIP Strategy measures such as the Advanced Clean Fleets and In-Use Locomotive Regulations will reduce mobile source emissions from heavy-duty trucks

and other sources around warehouses, railyards, and ports, as well as reducing other emissions, which in turn will reduce corresponding health risk in California's most impacted communities.

CARB prioritized public participation as an essential part of developing the measures included in the 2022 State SIP Strategy. CARB initiated the public process with a workshop in July 2021. After the workshop, CARB staff reached out to and met with a number of community-based organizations who provided input on the potential control measures. CARB released the 2022 State SIP Strategy: Draft Measures document which considered the input from the community-based organizations and comments during the first workshop.

CARB staff held a second workshop discussing the Draft Measures document in October 2021 and received additional input from a broad array of interested parties. The workshop presented a detailed discussion on the potential measures and allowed for the public and interested parties to comment on every facet of each potential measure. CARB staff also participated in the South Coast measure workshops as part of their SIP development process. CARB staff released the Draft 2022 State SIP Strategy in January 2022, prior to a third workshop, and presented an informational update to the Board at the Board Meeting in February 2022 to discuss and obtain public feedback. The input from numerous interested parties and community-based organizations framed the control measures in the Strategy such as the Zero-Emissions Trucks and Pesticide Measures.

These workshops and Board updates provided forums in both English and Spanish and afforded any special accommodations if requested to facilitate discussing the proposed measures in a public setting and to provide additional opportunity for public feedback, input, and ideas. And finally, CARB released the Proposed 2022 State SIP Strategy and hosted our 4th workshop in August 2022, prior to the CARB Board adopting the 2022 State SIP Strategy in September 2022. The workshops were well attended by a wide range of interested parties including community-based organizations. CARB staff listened to interested parties, evaluated their recommendations, and included some of these recommendations as measures that were appropriate for the 2022 State SIP Strategy. In order for a public suggestion to be included as a SIP measure, it needed to meet U.S. EPA-required integrity elements. SIP measures are required to be quantifiable, enforceable, surplus, and permanent. Measures suggested by the public that were ultimately adopted in the 2022 State SIP Strategy include a regulation to reduce emissions of reactive organic gas from pesticides in collaboration with the California Department of Pesticide Regulation and a zero-emission truck measure to help ensure that smaller trucking companies have more consistent access to zero-emission truck incentives.

Following the Board's approval of the 2022 State SIP Strategy, the public processes continue as each measure within the strategy goes through its own public process to engage with impacted communities and interested parties to further develop the measures prior to being brought to the Board for consideration as a regulation or other program. As development and implementation of these measures progress, CARB staff will continue to identify and implement opportunities to mitigate air pollution associated with racial inequities and meaningfully engage and partner with communities most impacted to address long standing disparities and challenges. As CARB cannot do this alone, CARB will also continue

to partner with other authorities such as air districts including the South Coast AQMD, other State agencies, and the federal government to ensure emissions reduction are achieved.

These connected efforts, as well as interagency efforts, will provide additional pathways to address Title VI requirements and support achieving the goal where zip code or race does not predict air pollution exposures. CARB has reviewed U.S. EPA and U.S. Department of Justice resources for Title VI and environmental justice policies, and looks forward to written guidance from U.S. EPA to address Clean Air Act section 110(a)(2)(E) as the State develops future clean air plans.

Civil Rights Policy and Discrimination Complaint Process

Under CARB's written Civil Rights Policy and Discrimination Complaint process (Civil Rights Policy), CARB has a policy of nondiscrimination in its programs and activities and implements a process for discrimination complaints filed with CARB, which is available on CARB's website. The Civil Rights Officer coordinates implementation of CARB's nondiscrimination activities, including as the Equal Employment Opportunity (EEO) Officer for employment purposes, and who can be reached at EEOP@arb.ca.gov, or (279) 208-7110.⁹

The Civil Rights Policy and Discrimination Complaint Process provides the following information about the nondiscrimination policy and its applicability:

It is CARB policy to provide fair and equal access to the benefits of a program or activity administered by CARB. CARB will not tolerate discrimination against any person(s) seeking to participate in, or receive the benefits of, any program or activity offered or conducted by CARB. Members of the public who believe they were unlawfully denied full and equal access to a CARB program or activity may file a civil rights complaint with CARB under this policy. This non-discrimination policy also applies to people or entities, including contractors, subcontractors, or grantees that CARB utilizes to provide benefits and services to members of the public. [. . .]

As described in the Civil Rights Policy and Discrimination Complaint Process, the Civil Rights Officer coordinates implementation of nondiscrimination activities:

CARB's Executive Officer will have final authority and responsibility for compliance with this policy. CARB's Civil Rights Officer, on behalf of the Executive Officer, will coordinate this policy's implementation within CARB, including work with the Ombudsman's Office, Office of Communications, and the staff and managers within a program or activity offered by CARB. The Civil Rights Officer coordinates compliance efforts, receives inquiries concerning non-discrimination requirements, and ensures CARB is complying with state and federal reporting

⁹ CARB. California Air Resources Board and Civil Rights. <https://ww2.arb.ca.gov/california-air-resources-board-and-civil-rights>, Civil Rights Policy and Discrimination Complaint Process. November 1, 2016. <https://ww2.arb.ca.gov/sites/default/files/2023-01/2016-11-03%20CARB%20Civil%20Rights%20Policy%20Revised%20Final.pdf>

and record retention requirements, including those required by Code of Federal Regulations, Title 40, Section 7.10 et seq.

The Civil Rights Policy and Discrimination Complaint Process also describes in detail the complaint procedure, as follows:

A Civil rights complaint may be filed against CARB or other people or entities affiliated with CARB, including contractors, subcontractors, or grantees that CARB utilizes to provide benefits and services to members of the public. The complainant must file his or her complaint within one year of the alleged discrimination. This one-year time limit may be extended up to, but no more than, an additional 90 days if the complainant first obtained knowledge of the facts of the alleged violation after the expiration of the one-year time limit. [. . .]

The Civil Rights Officer will review the facts presented and collected and reach a determination on the merits of the complaint based on a preponderance of the evidence. The Civil Rights Officer will inform the complainant in writing when CARB has reached a determination on the merits of the discrimination complaint. Where the complainant has articulated facts that do not appear discriminatory but warrants further review, the Civil Rights Officer, in his or her discretion, may forward the complaint to a party within CARB for action. The Civil Rights Officer will inform the complainant, either verbally or in writing, before facilitating the transfer. [. . .]

CARB will not tolerate retaliation against a complainant or a participant in the complaint process. Anyone who believes that they have been subject to retaliation in violation of this policy may file a complaint of retaliation with CARB following the procedures outlined in this policy.

There is a Civil Rights Complaint Form available¹⁰ on the webpage, which should be used by members of the public to file a complaint of discrimination against CARB that an individual believes occurred during the administration of its programs and services offered to the public. As described on CARB's webpage, for all complaints submitted, the Civil Rights Officer will review the complaint to determine if there is a prima facie complaint (which means, if all facts alleged were true, would a violation of the applicable policy exist). If the Civil Rights Officer identifies a prima facie complaint in the jurisdiction of the Civil Rights Office, the Civil Rights Office will investigate and determine whether there is a violation of the policy.

The laws and regulations that CARB implements through this policy include:

- Code of Federal Regulations, Title 40 Parts 5 and 7;
- Title VI of the U.S. Civil Rights Act of 1964, as amended;
- Section 504 of the Rehabilitation Act of 1973;

¹⁰ CARB. Civil Rights Complaint Form. July 2019. https://ww2.arb.ca.gov/sites/default/files/2023-01/eo_eeo_033_civil_rights_complaints_form.pdf

- Age Discrimination Act of 1975;
- Title IX of the Education Amendments of 1972;
- California Government Code, Title 2, Division 3, Part 1, Chapter 2, Article 9.5, *Discrimination*, Section 11135 et seq.; and
- California Code of Regulations, Title 2, Section 10000 et seq.

As part of its overarching civil rights and environmental justice efforts, CARB is in the process of updating its Civil Rights Policy and will make those publicly available once complete. These updates will reflect available U.S. EPA and U.S. Department of Justice resources for Title VI and environmental justice policies. CARB encourages U.S. EPA to issue additional guidance to further clarify Title VI requirements and expectations to assist state implementation efforts.

CARB's Mobile Source Measures

On-Road Heavy-Duty

Advanced Clean Fleets Regulation

The Advanced Clean Fleets Regulation was adopted by CARB on April 27, 2023. This measure accelerates zero-emission vehicle (ZEV) adoption in the medium- and heavy-duty sectors by setting zero-emission requirements for fleets and a 100 percent ZEV sales requirement in California for manufacturers of Class 2b through 8 vehicles starting in 2036. The Advanced Clean Fleets Regulation focuses on strategies that ensure the cleanest vehicles are deployed by government, business, and other entities in California while meeting their transportation needs. The requirements are phased-in on varying schedules for different fleets including drayage trucks, high priority private and federal fleets, and state and local government fleets. All drayage trucks operating at seaports and intermodal railyards are required to be zero-emission by 2035. Drayage trucks also have new registration and reporting requirements, starting in 2023. High priority private and federal fleets must only add ZEVs or near-zero-emission vehicles with minimum all electric range to the California fleet starting January 1, 2024. However, to provide flexibility, these fleets may opt into the ZEV milestone schedule which is a ZEV phase-in as a percentage of the California fleet and targets vehicles that are well suited for electrification starting in 2025. State and local government fleets are required to phase-in a ZEV purchase requirement starting at 50 percent of new purchases in 2024 and 100 percent starting in 2027 or these fleets may opt into the ZEV milestone schedule.

Zero-Emission Trucks Measure

This measure would increase the number of ZEVs and require cleaner engines to achieve emissions reductions from fleets that are not affected by the Advanced Clean Fleets Regulation. This would include potential zero-emissions zone concepts around warehouses and sensitive communities if CARB is given

new authority to enact indirect source rules in combination with strategies to upgrade older trucks to newer and cleaner engines. This would be a transitional strategy to achieve zero-emissions medium- and heavy-duty vehicles everywhere feasible by 2045.

On-Road Light-Duty

Clean Miles Standard

The Clean Miles Standard was adopted by CARB on May 20, 2021. The primary goals of this measure are to reduce GHG emissions from ride-hailing services offered by transportation network companies (TNCs) and promote electrification of the fleet by setting an electric vehicle mile target, while achieving criteria pollutant co-benefits. TNCs would be required to achieve zero grams CO₂ emissions per passenger mile traveled and 90 percent electric VMT by 2030.

Off-Road Equipment

Tier 5 Off-Road Vehicles and Equipment

This measure would reduce NO_x and particulate matter (PM) emissions from new off-road compression-ignition (CI) engines by adopting more stringent exhaust standards for all power categories, including those that do not currently utilize exhaust aftertreatment such as diesel particulate filters and selective catalytic reduction. This measure would be more stringent than required by current CARB, U.S. EPA and European Stage V nonroad regulations and would require the latest generations of emission control technologies.

For this measure, CARB staff would develop and propose standards for new off-road CI engines including the following: lower PM standards for engines less than 19 kilowatt (kW) (25 horsepower [hp]), lower NO_x and PM standards for engines greater than or equal to 19 kW (25 hp) and less than 56 kW (75 hp), and more stringent aftertreatment-based PM and NO_x standards for engines greater than or equal to 56 kW (75 hp). Other possible elements include new manufacturer-based in-use testing requirements, proposing more representative useful life periods, and developing a low load certification test cycle. It is expected that this comprehensive offroad Tier 5 regulation would rely heavily on technologies that manufacturers are developing to meet the recently approved low NO_x standards and enhanced in-use requirements for on-road heavy-duty engines.

Amendments to the In-Use Off-Road Diesel-Fueled Fleets Regulation

The amendments to the In-Use Off-Road Diesel-Fueled Fleets Regulation were adopted by CARB on November 17, 2022. This measure further reduces NO_x and PM emissions from the in-use off-road diesel equipment sector by adopting more stringent requirements that target the oldest and dirtiest equipment that were previously allowed to operate indefinitely.

The amendments include a phase out schedule for most Tier 0, 1, and 2 engines between 2024 and 2036. This will allow a 12-year phase out of these oldest engines. Along with the engine tier phase out, adding vehicle provisions in the current regulation are extended to phase in a restriction on the adding of vehicles with Tier 3 and Tier 4 interim engines to fleets. The amendments also include new requirements for fleets to use renewable diesel (with some limited exemptions), new contracting requirements for prime contractors and public works awarding bodies to increase the enforceability and awareness of the regulation, and two optional flexibility provisions for fleet adoption of zero_-emission vehicles. Additional modifications include clarifications to implementation, sunset of year-by-year low use, the addition of flexibility to permanent low-use, and the sunset of a provision that would have allowed small fleets to continue to operate vehicles that could not be retrofitted with a verified diesel emission control strategy indefinitely.

Transport Refrigeration Unit Regulation Part 2 (Non-Truck TRUs)

This measure is the second part of a two-part rulemaking to transition diesel-powered transport refrigeration units (TRUs) to zero_-emission technologies. This measure would require zero_-emission equipment for non-truck TRUs (trailer TRUs, domestic shipping container TRUs, railcar TRUs, and TRU generator sets).

Commercial Harbor Craft Amendments

The amendments to the Commercial Harbor Craft Regulation were adopted by CARB on March 24, 2022. The amended regulation requires that starting in 2023 and phasing in through 2031, most commercial harbor crafts (CHCs) (except for commercial fishing vessels and categories listed below) are required to meet the cleanest possible standard (Tier 3 or 4) and retrofit with diesel particulate filters (DPFs) based on a compliance schedule. The prior regulated CHC categories are ferries, excursion, crew and supply, tug/tow boats, barges, and dredges. The amendments impose in-use requirements on the rest of vessel categories except for commercial fishing vessels, including workboats, pilot vessels, commercial passenger fishing, and all barges over 400 feet in length or otherwise meeting the definition of an ocean-going vessel. The amendments require engines on new build commercial fishing vessels to meet the most stringent marine standards (Tier 3 or Tier 4) or Tier 4 Final off-road emission standards. The amendments also remove the exemption for engines less than 50 hp.

The regulation also requires that, starting in 2025, all new and newly acquired excursion vessels to be plug-in hybrid vessels that are capable of deriving 30 percent or more of combined propulsion and auxiliary power from a zero_-emission tailpipe emission source. Starting in 2026, all new, newly acquired and in-use short run ferries are required to be zero_-emission; and starting in 2030 and 2032, all in-use commercial fishing vessels would need to meet a Tier 2 standard at minimum.

Cargo Handling Equipment Amendments

This measure would start transitioning Cargo Handling Equipment (CHE) to full zero_-emission by 2030, with over 90 percent penetration of ZE equipment by 2036. Based on the current state of zero_-emission

CHE technological developments, the transition to zero-emission would most likely be achieved largely through the electrification of CHE. This assumption about aggressive electrification is supported by the fact that currently some electric RTG cranes, electric forklifts, and electric yard tractors are already commercially available. The zero-emission phase-in schedule will be determined by technology feasibility determinations and discussions with public stakeholders during the rulemaking process.

Other

Zero-Emission Standard for Space and Water Heaters

For this measure, CARB would develop and propose zero-emission GHG standards for new space and water heaters sold in California; CARB could also work with air districts to further tighten district rules to drive zero-emission technologies. This measure would not mandate retrofits in existing buildings, but some buildings would require retrofits to be able to use the zero-emission technology that this measure would require. Beginning in 2030, 100 percent of sales of new space and water heaters (for either new construction or replacement of burned-out equipment in existing buildings) would need to meet zero-emission standards. It is expected that this regulation would rely heavily on heat pump technologies currently being sold to electrify new and existing buildings.

Primarily-Federally and Internationally Regulated Sources – CARB Measures

In addition to reducing emissions from the above sources, it is critical to achieve emissions reductions from sources that are primarily regulated at the federal and international level. It is imperative that the federal government and other relevant regulatory entities act decisively to reduce emissions from these primarily-federally and internationally regulated sources of air pollution. CARB and the air districts in California have taken actions to not only petition federal agencies for action, but also to directly reduce emissions using programmatic mechanisms within our respective authorities. CARB continues to explore additional actions, many of which may require a waiver or authorization under the Clean Air Act, as described below.

In-Use Locomotive Regulation

The In-Use Locomotive Regulation was adopted by CARB April 27, 2023. This measure uses mechanisms available under CARB's regulatory authority to accelerate the adoption of advanced, cleaner technologies, and include zero-emission technologies, for locomotive operations. The In-Use Locomotive Regulation applies to all locomotives operating in the State of California with engines that have a total rated power of greater than 1,006 horsepower, excluding locomotive engines used in training of mechanics, equipment designed to operate both on roads and rails, and military locomotives. The measure reduces emissions by increasing use of cleaner diesel locomotives and zero-emission locomotives through a spending account, in-use operational requirements, and by an idling limit. By July 1, 2024, a spending account is established for each locomotive operator. Funds in the account is only to be used toward Tier 4 or cleaner locomotives

until 2030, and at any time toward zero-emission locomotives, zero-emission pilot or demonstration projects, or zero-emission infrastructure.

For the in-use operational requirements, beginning January 1, 2030, only locomotives built after January 1, 2007, may operate in California. Each year after January 1, 2030, only locomotives less than 23 years old may operate in California. Additionally, under the in-use operational requirements, starting January 1, 2030, all switch, industrial, and passenger locomotives operating in California with an original engine build date 2030 or newer will be required to be zero-emission. Starting January 1, 2035, all freight line haul locomotives operating in California with an original engine build date 2035 or newer must be zero-emission. Locomotives equipped with automatic engine stop/start systems are to idle no more than 30 minutes unless an exemption applies. Also, locomotive operators would report locomotive engine emissions levels and activity on an annual basis.

U.S. EPA's Clean Trucks Rule

Effective March 27, 2023, the U.S. EPA adopted a final rule titled “Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards.”¹¹ This rule is part of the U.S. EPA's Clean Trucks Plan (CTP) that aims to reduce ozone and PM_{2.5} air pollution from heavy-duty trucks and buses. The rule applies to manufacturers of heavy-duty engines and vehicles. It will result in lower NO_x emissions from new heavy-duty vehicles beginning in model year (MY) 2027 by setting more stringent emission standards that cover a wider range of heavy-duty engine operating conditions and require those standards to be met for a longer period of time of when these engines operate on the road. The rule also changes key provisions of the existing heavy-duty vehicle emission control program, such as the test procedures, regulatory useful life, emission-related warranty, and other requirements. U.S. EPA's CTP will result in emission benefits by 2030 and South Coast AQMD includes those benefits as a line item adjustment to the baseline emissions in this PM_{2.5} Plan (see Table 4-12).

SCAG's Regional Transportation Plan/Sustainable Communities Strategy and Transportation Control Measures

The PM_{2.5} Plan includes Transportation Control Measures (TCMs) from Southern California Association of Government's (SCAG) Regional Transportation Plan/Sustainable Communities Strategy to address attainment of the 2012 annual PM_{2.5} standard in the South Coast Air Basin. The TCMs are based on SCAG's Final 2020–2045 Regional Transportation Plan/Sustainable Communities Strategy (2020 RTP/SCS, also known as Connect SoCal) and 2023 Federal Transportation Improvement Program (FTIP), as amended.

¹¹ Control of Air Pollution From New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, 88 Fed. Reg. 4296 (January 24, 2023)

The RTP/SCS and FTIP were developed in consultation with federal, state and local transportation and air quality planning agencies and other stakeholders. The four County Transportation Commissions (CTCs) in the South Coast Air Basin, namely Los Angeles County Metropolitan Transportation Authority, Riverside County Transportation Commission, Orange County Transportation Authority and the San Bernardino County Transportation Authority, were actively involved in the development of the regional transportation measures of this Appendix. While SCAG will soon adopt the 2024 RTP/SCS, this PM2.5 Plan is based on the 2020 RTP/SCS as it was the latest approved RTP/SCS at the time of plan development. Refer to Appendix IV-B for more details.

SIP Emission Reduction Commitment

The SIP emission reduction commitment in the PM2.5 Plan reflects the estimated emission reductions from adopted rules and proposed measures. These are the emission reductions that we use to show progress in reducing emissions in an expeditious manner, and how the region will be able to meet the 2012 annual PM2.5 standard. Not all emission reductions that occur are SIP-creditable – meaning they do not count for purposes of showing how an area will be able to meet federal air quality standards. To be SIP-creditable, emission reductions must meet specific U.S. EPA criteria (e.g., integrity elements) to provide confidence that the emission reductions relied upon to meet the standards will occur. The following sections first describe the methodology for calculating SIP emissions and SIP-creditable reductions, then describe what procedures will be followed to ensure fulfillment of the commitment.

SIP Emission Reduction Tracking

For purposes of tracking progress in emission reductions, the baseline annual average emissions for the year 2030 will be used, regardless of any subsequent new inventory information that may reflect more recent knowledge. This is to ensure that the same “currency” is used in measuring progress as was used in designing the AQMP and that there is an “apples to apples” comparison in evaluating emissions.

Any emission reductions achieved beyond the existing South Coast AQMD regulations are creditable only if there is also a mechanism to ensure that the commitments to achieve those emission reductions are enforceable. Therefore, in certain instances, the South Coast AQMD may have to adopt regulations to reflect the existing industry practices in order to claim SIP reduction credit, with the understanding that there may not be additional reductions beyond what has already occurred. Exceptions can be made where reductions are real, quantifiable, surplus to the baseline inventory, and enforceable through other State and/or federal regulations. Further, any emission inventory revisions, which have gone through a peer review and public review process, can also be SIP creditable.

The PM2.5 Plan includes emission reductions from voluntary incentive measures to help meet the 2012 annual PM2.5 standard. With reliance on voluntary incentive measures to achieve attainment of the federal PM2.5 standard and for those measures to be SIP-approved, the South Coast AQMD must design programs such that the emission reductions from these incentive measures are proven to be real, quantifiable, surplus, enforceable, and permanent.

There are key components required of a SIP submittal in order to rely on discretionary incentive programs to satisfy the CAA emission reduction requirements. These components include a demonstration addressing the “integrity elements” (the five requirements listed above), federally enforceable “backstop” commitments, technical support, funding, legal authority, public disclosure and provisions to track results that are common among the various voluntary incentive programs. The “backstop” commitments include a requirement to monitor emission reductions achieved by the voluntary incentive measures and to report annually to the U.S. EPA the amount of reductions achieved. If the U.S. EPA determines that insufficient progress has been made, then substitute measures must be implemented to rectify the shortfall prior to the statutory implementation deadline. The South Coast AQMD is committed to developing detailed guidelines for voluntary incentive programs for individual incentive measures in accordance with the U.S. EPA’s economic incentive programs guidelines. The following section describes the necessary criteria that will be included in each of the incentive measures.

Integrity Elements to Ensure Emission Reductions from Incentive Programs

To be SIP-creditable, emission reductions from voluntary incentive measures must meet the U.S. EPA’s integrity elements. The emission reductions must be real, quantifiable, surplus, enforceable, and permanent. This demonstration must include project type(s); project life; applicable incentive program guidelines by title and year; and analysis of applicable incentive program guidelines for consistency with the integrity elements. For the purposes of this demonstration, the following defines and provides examples of the key elements:

Quantifiable

Emission reductions are quantitatively measurable, supported by existing and acceptable technical data. The quantification should use well-established, publicly available, and approved emission factors and accepted calculation methodology. There must be procedures to evaluate and verify over time the level of emission reductions that are actually achieved.

Surplus

Emission reductions must be above and beyond all current and known future District, State, or federal regulations already included in the SIP. Annual tracking will account for any potential overlapping future regulations that could conflict with the surplus reductions. Emission reductions used to meet air quality attainment requirements are surplus as long as they are not otherwise relied on in the SIP, SIP-related requirements, and other State air quality programs adopted but not in the SIP, a consent decree, or federal rules that focus on reducing criteria pollutants or their precursors. In the event that a voluntary incentive program’s emission reductions are already relied on to meet air quality-related program requirements, they are no longer surplus. In addition, the emission reductions are available only for the remaining useful life of the equipment being replaced (e.g., if the equipment being replaced had a remaining useful life of five years, the additional emission reductions from the new equipment are available for SIP or conformity purposes under this guidance only for five years).

Enforceable

The South Coast AQMD will be responsible for assuring that the emission reductions credited in the SIP will occur. Emission reductions and other required actions are enforceable if:

- a. They are independently verifiable;
- b. Program violations are defined;
- c. Those liable for emission reductions can be identified;
- d. The South Coast AQMD and the U.S. EPA maintain the ability to apply penalties and secure appropriate corrective action where applicable;
- e. The general public has access to the emissions-related information obtained from the source;
- f. The general public can file suits against sources for violations (with the exception of those owned and operated by Tribes); and
- g. They are practically enforceable in accordance with other U.S. EPA guidance on practicable enforceability.

Actual emission reductions, for example, can be assured through replacement equipment registration, recordkeeping and reporting, and inspections (initial inspection after installation and subsequent inspections on a regular basis thereafter, if needed) throughout the term of project. Specific enforcement mechanisms will be addressed in the guidelines for the individual incentive measures.

Permanent

The emission reductions are permanent if they occur over the duration of the voluntary incentive program, and for as long as they are relied on in the SIP. For example, those awarded incentives would need to ensure the projects are properly implemented and the reductions are occurring and will continue to occur. Recipients of the incentive awards would therefore agree to contract provisions, such as recordkeeping and reporting to track reductions and agreements that newly installed equipment would not be removed without concurrence of the South Coast AQMD (i.e., permanent placement) and the proof that the replaced equipment would be destroyed or at least not be operated in the Basin (e.g., pictures, certification). Detailed procedures to ensure permanent reductions will be described in the guidelines for the individual incentive measures.

Reductions from South Coast AQMD Control Measures

For purposes of implementing an approved SIP, the South Coast AQMD is committed to adopt and implement control measures that will achieve, in aggregate, emission reductions to demonstrate expeditious progress toward meeting the federal 2012 annual PM_{2.5} standard. The South Coast AQMD is

committed to adopt the control measures in Tables 4-2 and 4-3 unless these measures or a portion thereof are found infeasible, and other substitute measures that can achieve equivalent reductions in the same adoption or implementation timeframes are adopted. Findings of infeasibility will be made at a regularly scheduled meeting of the South Coast AQMD Governing Board with proper public notification. For purposes of the SIP commitment, infeasibility means that the proposed control technology is not reasonably likely to be available by the implementation date in question, or achievement of the emission reductions by that date is not technically or economically feasible. The reductions in Tables 4-2 and 4-3 are committed only to the extent needed to achieve attainment by the 2030 attainment deadline. If any substitution is needed, the alternative measures will need to achieve the same emission reductions or air quality benefit. The aggregate emission reduction commitments, along with the anticipated specific control measures to meet that reduction commitment are made with the understanding that if there is a shortfall in the individual measures for a particular year, emission reductions from other control measures could be substituted. The South Coast AQMD acknowledges that this commitment is enforceable under CAA section 304(f). The U.S. EPA will not credit SIP reductions unless the control measures are adopted and approved into the SIP at the time the U.S. EPA takes action on the plan.¹²

Reductions from CARB Control Measures

The CARB proposed control measures presented in Table 4-6, combined with ongoing implementation of current control programs, will provide further reductions to enhance air quality progress and achieve the 2012 annual PM2.5 standard.

Overall Emission Reductions

Table 4-12 identifies projected reductions for the South Coast Air Basin based on the annual inventory for NOx and direct PM2.5 emissions for 2030 and Table 4-13 summarizes total reductions from 2018 base year to 2030 attainment. These reductions reflect the emission reductions associated with implementation of control measures under State and local jurisdiction. Table 4-12 also includes emission reductions from recently adopted regulations as line item adjustments. South Coast AQMD and CARB commit to reduce NOx and PM2.5 emissions by 9.99 tpd and 0.53 tpd, respectively, beyond the 2030 baseline emissions through control measures proposed in this PM2.5 Plan. This enforceable commitment represents 5 percent and 16 percent, respectively, of the overall NOx and PM2.5 reductions that will occur between 2018 and 2030. Both the enforceable commitment and attainment demonstration exclude emission reductions from control measures that are needed to satisfy MSM requirements, as these requirements are independent of attainment.

¹² U.S. EPA has in the past allowed about 10 percent of required reductions to be in the form of “enforceable commitments”

CHAPTER 5

Future Air Quality

- Modest additional emission reductions are required for the Basin to attain the 2012 annual PM_{2.5} standard in 2030.
- The emissions of direct PM_{2.5}, NO_x, and ammonia must be reduced by 1.4, 34.9, and 3.2 tons per day respectively, beyond the 2030 baseline levels to attain the standard in 2030.
- The control strategy discussed in Chapter 4 provides a path to attain the standard by 2030, with a design value at our highest monitoring site of 12.0 µg/m³.
- With the control strategy outlined in Chapter 4 of this Plan, it is anticipated that annual PM_{2.5} levels in all areas of the Basin will be below 12.0 µg/m³ by 2030.

Introduction

The primary objective of the 2024 PM_{2.5} Plan is to address attainment of the federal 2012 annual average PM_{2.5} standard, set at 12 µg/m³. Air quality modeling to demonstrate future attainment of the PM_{2.5} standard is an integral part of the planning process to achieve clean air. Attainment demonstration is the modeling exercise that shows how emission reductions will result in lower concentrations of air pollutants, presenting the path to attainment. The demonstration reflects updated emissions estimates, new technical information, enhanced air quality modeling techniques, updated attainment demonstration methodology, and the control strategy.

Base Design Value

A design value is a statistical metric used to show whether a region is in attainment with the NAAQS. The base design value is the starting point of the modeling analysis to show the pathway to attainment. U.S. EPA guidance recommends the use of multiple year averages of design values where appropriate in establishing the base design value. This approach helps mitigate the impacts of single-year anomalies on air quality trends, which may arise due to factors including exceptional or adverse meteorological conditions or radical changes in local emissions profiles. The trend in the Basin's annual PM_{2.5} design values, determined from routine Federal Reference Method (FRM) samples, from 2001 through 2022 reveal substantial reductions in concentrations over this timeframe (see Figure 5-1). However, it's noteworthy that the rate of decrease in annual design values has decelerated since 2012.

*Data likely to be approved as exceptional events by U.S. EPA removed from analysis.

FIGURE 5-1
SOUTH COAST AIR BASIN ANNUAL PM_{2.5} DESIGN VALUES FROM 2001 TO 2022

Overall, since 2001, the annual PM_{2.5} design values have decreased by over 50%, from 30 µg/m³ in 2001 to 13.7 µg/m³ in 2022. The deceleration in PM_{2.5} reduction in recent years can be attributed to a variety of factors, including meteorology, increased activities at ports, and additional sources of PM_{2.5} precursors. Additionally, in January 2015, two new near-road monitors started operating and providing valid data: the Ontario CA-60 and the Long Beach I-710 near-road monitors. PM_{2.5} concentrations are often higher at near road monitors, reflecting higher levels of resuspended dust, vehicle exhaust and brake and tire wear. Since 2017, the Ontario CA-60 near-road station has served as the design site in the basin.

Modeling Base Design Value Calculation

The PM_{2.5} annual design value for a specific year is determined by averaging the annual PM_{2.5} concentrations over a three-year period that includes the given year and the two preceding years. However, U.S. EPA guidance on modeling the attainment demonstration¹ recommends using a 5-year weighted design value centered on the base year selected for the attainment demonstration as the modeling Base Design Value (DVB). This 5-year weighted average approach recommended by EPA is to reduce year-to-year variability compared to a single 3-year design value. In the context of this plan, the DVB for each monitoring station is calculated as the average of the design values for 2018 through 2020 (denoted as DV 2018, DV 2019, and DV 2020 in Figure 5-2). This calculation covers a 5-year period from 2016 through 2020, centered at the base year 2018. Under certain circumstances, the U.S. EPA allows modification of DVB calculation, such as in the case of exceptional events. Figure 5-2 presents the U.S. EPA-recommended DVB calculation on the left. The 2020 DV calculation includes the year 2020, which was marked by several extraordinary events that significantly altered PM_{2.5} concentrations in the basin. These events include the COVID-19 pandemic and associated changes in human activity, and record-setting wildfires. More details on the exceptionality of 2020 are discussed in Chapter 5 of Appendix II. To address this anomalous year this PM_{2.5} plan uses a modified DVB for 2018 that excludes the 2020 DV from DVB calculations and replaces it with the average of 2018 and 2019 annual means (Figure 5-2, right). In addition, exceptional events on July 4 and 5 due to Fourth of July fireworks are also excluded. Justification to exclude these days from DVB calculations is included in Appendix II.

U.S. EPA'S DEFAULT METHODOLOGY (LEFT PANEL) AND MODIFIED METHODOLOGY TO
EXCLUDE YEAR 2020 (RIGHT PANEL). DV REFERS TO A 3-YEAR DESIGN VALUE.

Table 5-1 shows the annual 2018 DVB values for all monitoring stations within the Basin, and it includes the 2012 DVB presented in the 2016 AQMP. Notably, the Ontario CA-60 near-road monitor has the highest design value in 2018 (13.98 µg/m³) making it the designated design site for this PM2.5 plan. Mira Loma was the design site in the 2016 AQMP before data from the Ontario CA-60 near-road was available, but its DVB in 2018 is the second highest, with a decline from 14.87 µg/m³ in 2012 to 13.53 µg/m³. In general, the stations reported in the 2016 AQMP experienced a decrease in DVB from 2012 to 2018. While the DVB values for 2012 included the exceptional events of Fourth of July fireworks, which might amplify the reductions in DVB from 2012 to 2018 slightly, trends show that the annual PM2.5 concentrations keep improving.

PM_{2.5} Speciation

PM_{2.5} species profiles for the base year are required to project future design values of PM_{2.5}. The PM_{2.5} species required in the calculation of future design values are the following: sulfate (SO₄), nitrate (NO₃), ammonium (NH₄), elemental carbon (EC), sea salts (Salt), crustal species, organic carbon (OC), particle-bound water (PBW), and a blank. There are a total of four monitoring stations from the Chemical Speciation Network (CSN) that routinely measure PM_{2.5} speciation data in the Basin. These CSN monitors are collocated where their corresponding FRM monitors are located. With one site in each county, the

four CSN sites are strategically located to represent aerosol characteristics in the four counties within the Basin. Historically, Riverside-Rubidoux served as the design site, a location with the highest annual PM_{2.5} concentration in the Basin. Fontana and Anaheim experienced elevated concentrations within their respective counties, and the Central Los Angeles site was intended to capture the characteristics of an emission source area.

The measurements of individual species obtained from the CSN sites may differ from the retained mass of a specific species in the FRM filter, due to the inherent differences in the measurement techniques. To reconcile the expected differences between speciated and FRM measurements, species are adjusted following the SANDWICH method², which is described in the U.S. EPA modeling guidance.³ This adjustment results in reduced nitrates (relative to the amount measured by routine speciation networks), higher mass associated with sulfates and nitrates (reflecting water included in gravimetric FRM measurements), and an estimate of organic carbonaceous mass, which is derived from the difference between FRM-measured PM_{2.5} and the sum of all components except measured organic carbon. EPA's mass balance method sets a ceiling for OC mass (OCM) to be 80 percent of the total PM_{2.5} mass. However, based on scientific literature on PM_{2.5} speciation data taken in the greater Los Angeles area,^{4,5} this ceiling was set as the 50 percent of PM_{2.5} FRM mass. EPA's guidance also sets a floor value for OCM to be the measured OC value. However, the sum of individual species measured from CSN is sometimes larger than the FRM mass. Under this condition, the measured OC as floor would erroneously exaggerate the OC fraction while reducing the other species, therefore, the OC floor was scaled by the ratio of FRM mass divided by the total CSN mass.

Directly measured ammonium (associated with nitrate and sulfate) at CSN stations, which is equivalent to particulate ammonium retained on FRM filters, was used for the speciation profiles. These measurements, however, were capped with fully neutralized ammonium, which is calculated as follows:

$$\text{Ammonium ceiling} = 0.375 \times \text{sulfate} + 0.29 \times \text{retained nitrate}$$

PBW was estimated using a polynomial regression equation fitted to the equilibrium model Aerosol Inorganic Matter (AIM) as a function of sulfate, nitrate, and adjusted ammonium concentrations. Most

FRM monitors in the Basin lack a co-located CSN monitor. Thus, as recommended by EPA guidance⁶, the individual speciation components from nearby CSN monitors were interpolated to the locations of FRM monitors that do not have a co-located CSN monitor using Inverse Distance Squared Weights. The interpolated speciated component at a given unmonitored location in the Basin is calculated using a weighted average of CSN monitor values, with weights of a monitor calculated as a function of the inverse squared distance from said monitor.

Figure 5-3 and Figure 5-4 compare PM_{2.5} speciation fraction profiles estimated for the 2016 AQMP and the current Draft PM_{2.5} Plan at the Central LA and Riverside-Rubidoux monitoring stations, respectively. Speciated monitor data from 2017 through 2019 was used for the Draft PM_{2.5} Plan speciation fraction profile, while the 2016 AQMP speciation profile was calculated using the data collected in 2012. Generally, nitrate, elemental carbon (EC), and ammonium fractions have declined between the 2016 AQMP and the Draft PM_{2.5} Plan across all seasons. This reduction reflects the effect of existing rules and regulations aimed at reducing primary PM_{2.5} and its precursor emissions.

Annual PM2.5 Modeling Approach

Simulations for PM2.5 concentrations were conducted for the 2018 base year and the 2030 attainment year. CMAQ simulations covered the entire year of 2018 (from January 1st to December 31st). These simulations encompassed 8,760 consecutive hours from which daily 24-hour average PM2.5 concentrations were calculated. PM2.5 is divided into primary particles – which are directly emitted into the atmosphere – and secondary particles – which are formed from precursor gases. Sources of primary PM2.5 include but are not limited to road dust, diesel soot, and combustion products. Secondary products, such as sulfates, nitrates, and complex organic carbon compounds, are formed through chemical reactions involving oxides of sulfur (SOx), oxides of nitrogen (NOx), VOCs, and ammonia (NH3). The following section summarizes the PM2.5 modeling approach adopted for this Plan. The comprehensive modeling system used for this Plan includes photochemical reactions involved in the formation of PM2.5, horizontal and vertical transport, and removal mechanisms such as deposition. More detailed information on the PM2.5 modeling is presented in Appendix II.

Meteorology, Emissions, and Air Quality Model Configuration

The emissions inventory and meteorological conditions were developed for 2018, which was selected as the base year for emissions and meteorology. U.S. EPA requires the base year to be one of the three years

of which DV was used in designation/re-classification,⁷ and 2018 was the year that U.S. EPA relied on to re-classify the Basin from “moderate” to “serious” non-attainment area.⁸ In addition, the Multiple Air Toxics Exposure Study V (MATES V)⁹ conducted during 2018 involved comprehensive monitoring and numerical modeling. This effort contributed to the development of a robust dataset to evaluate modeling performance and to improve capabilities for modeling year 2018.

The PM_{2.5} Plan attainment demonstration framework is an upgrade from the modeling platform used in the 2022 AQMP and more recent SIP revisions. The framework uses the U.S. EPA-supported CMAQ modeling platform (version 5.3.3), incorporating the Statewide Air Pollution Research Center (SAPRC) 07 chemistry, and uses meteorological fields from the Weather Research and Forecasting Model (WRF). The modeling platform tracks primary pollutants, including precursors of ozone and particulate matter (PM_{2.5}) as well as the formation of secondary pollutants like ozone and particles that result from chemical reactions occurring in the atmosphere. The simulations were conducted over an area with a western boundary over 100 miles west of the Ports of Los Angeles and Long Beach. The eastern boundary extends slightly beyond the Colorado River, while the northern and southern boundaries of the domain extend to the San Joaquin Valley and the Northern portions of Mexico, respectively. CMAQ was performed at a 4 km by 4 km grid resolution. For the PM_{2.5} Plan, WRF was updated to the most recent version (4.4.2) available at the time of protocol preparation. The WRF simulations were initialized using National Centers for Environmental Prediction (NCEP) re-analysis data¹⁰ and run for three-day increments with four-dimensional data assimilation (FDDA).

Spatial and temporal allocation of emissions followed the same methodology used in the 2022 AQMP. Point source emissions were extracted from the South Coast AQMD’s Annual Emissions Reporting Program and were allocated to specific days of the year using temporal allocation factors developed by CARB. On-road mobile source emissions were calculated using CARB’s EMFAC2021 emissions model, incorporating vehicle travel activity data provided by Southern California Association of Governments (SCAG). Vehicle emissions accounted for meteorological effects on operational and evaporative emissions (temperature and relative humidity effects) which were derived from daily meteorological variables predicted with WRF. In addition, hourly vehicle activity profiles based on the California Department of Transportation (Caltrans) Performance Measurement System (PeMS) were used to refine the temporal variation of vehicle emissions. Spatial and temporal allocation of emissions from area sources and most off-road emissions sources were calculated using the latest spatial and temporal surrogates developed by CARB, which were released in January 2021. In addition, ocean-going vessel emissions were spatially allocated using data from the Automated Identification System (AIS), and aircraft emissions from major airports within the basin were allocated using aircraft location information data derived from the Aircraft Communication Addressing and Reporting System (ACARS). Gridded hourly biogenic emissions were calculated using the Model of Emissions of Gases and Aerosols from Nature version 3.0 (MEGAN3.0)

driven by the meteorological inputs from WRF. More details on the modeling approach, data retrieval, model development and enhancement, model application, emissions inventory development, and interpretation of results is presented in Appendix II.

Design Values and Relative Response Factors (RRF)

To bridge the gap between air quality model predictions and measurements, U.S. EPA guidance¹¹ has recommended the use of relative response factors (RRFs). In this approach, future year concentration predictions require two elements: base year design values and RRFs. The RRF is simply a ratio of the future year predicted air quality to the simulated air quality in the base year, representing the model predicted change in air quality in response to predicted emissions changes. For the annual PM_{2.5} attainment demonstration, base year and future modeled concentrations are calculated as a quarterly average of a 3-by-3 grid centered at each station for each specific component. The ratio of base to future year quarterly mean concentrations for each component is the RRF for that component. Individual RRFs are calculated for NH₄, NO₃, SO₄, EC, OC, salt, and a combined grouping of crustal compounds and metals (Others). Future year design values were calculated by multiplying species- and site-specific RRFs by the corresponding quarterly design values. Once the future values for NH₄, NO₃ and SO₄ are calculated using RRFs, future PBW quarterly values are computed using the same polynomial fitting used in the SANDWICH method. The total future quarterly values at each site are then calculated by adding all the individual components and the blank. The four quarterly average concentrations are then averaged at each site to determine the future annual design values.

Model Performance Evaluation

The U.S. EPA recommends operational evaluations to assess how accurately the model predicts observed concentrations. The basis for this recommendation is that if the model can characterize base year PM_{2.5}, then greater confidence can be placed in the model-prediction of future concentrations. Figure 5-5 depicts the modeled and measured daily PM_{2.5} concentrations at stations of Los Angeles, Compton, Mira Loma, and Ontario CA-60 near-road during January 1 through December 31 of 2018. PM_{2.5} mass was measured every day for all stations in this Figure, except Compton at which PM_{2.5} was measured every three days. CMAQ predicts daily PM_{2.5} mass and seasonal variation of PM_{2.5} reasonably well with overestimation in winter months and underestimation in summer months. A comprehensive model performance evaluation for PM_{2.5}, NH₄, NO₃, SO₄, organic matter (OM), EC, and crustal species concentrations is presented in Appendix II.

Figure 5-6 shows the modeled (orange) and measured (blue) annual PM_{2.5} species concentrations at Anaheim, Central Los Angeles, Fontana, and Riverside in 2018. The model tends to overestimate

¹¹ Modeling Guidance for Demonstrating Attainment of Air Quality Goals for Ozone, PM and Regional Haze. Available at: https://www.epa.gov/sites/default/files/2020-10/documents/draft-o3-pm-rh-modeling_guidance-2014.pdf

concentrations at Central Los Angeles, which is near major sources of emissions. Conversely, the model tends to underestimate PM_{2.5} species concentrations at inland stations in Fontana and Riverside. Overall, the model predicts NH₄ ion, SO₄, nitrate, EC, and OM concentrations reasonably well. Model results accurately capture the relative contributions of PM_{2.5} species and show that nitrate and OM are the largest contributors to total PM_{2.5}.

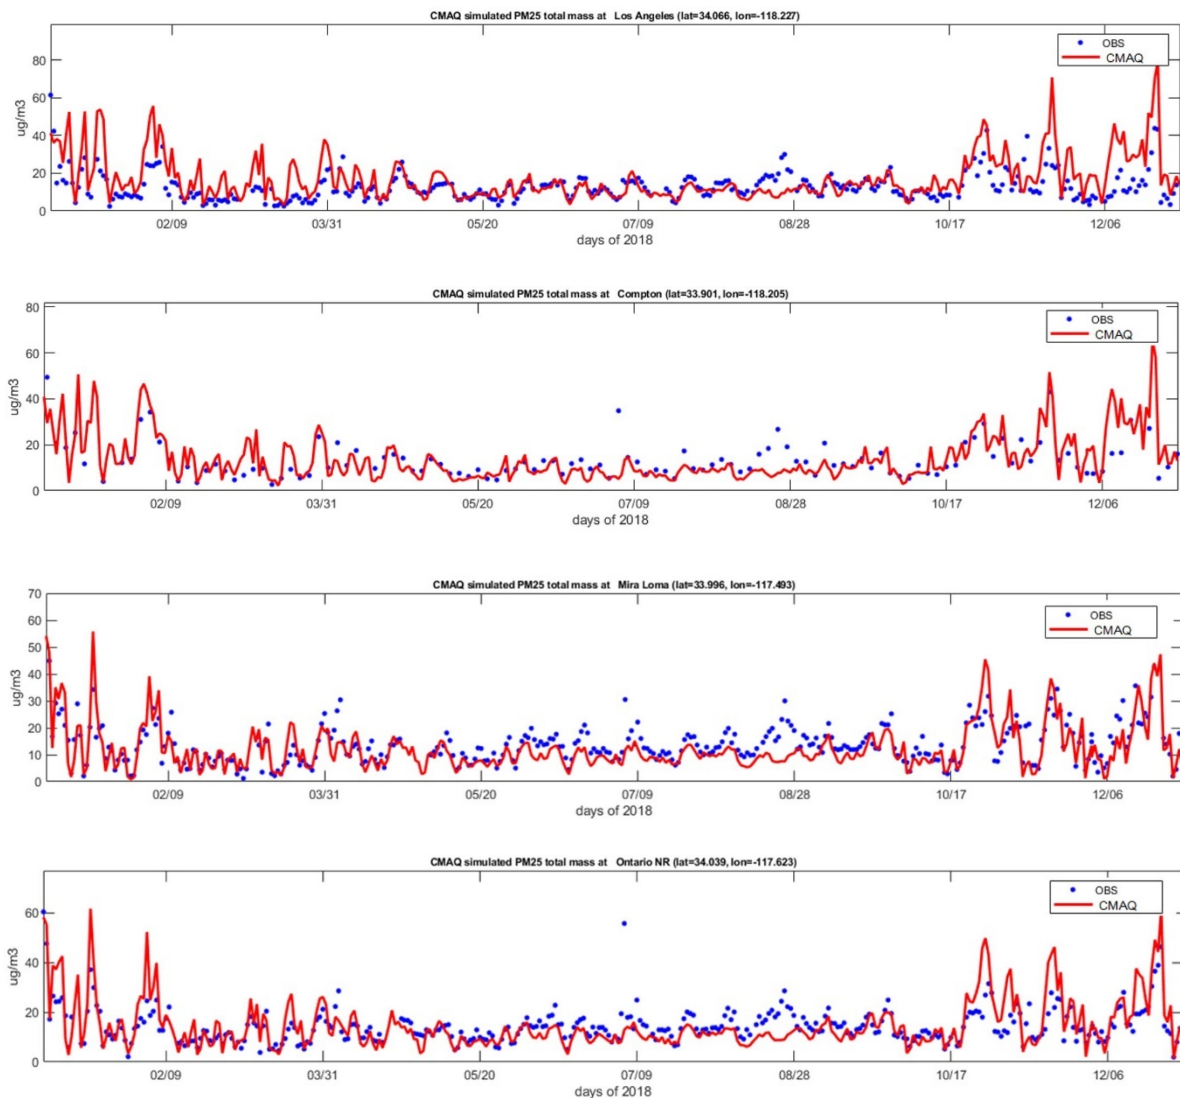

FIGURE 5-5

MODELED (ORANGE) AND OBSERVED (BLUE) ANNUAL PM_{2.5} SPECIES CONCENTRATIONS IN
ANAHEIM (ANAH), CENTRAL LOS ANGELES (CELA), FONTANA (FONT), RIVERSIDE (RIVR)
DURING 2018**

Figure 5-7 shows the modeled (orange) and observed (blue) seasonal variation of nitrate and OM concentrations at Anaheim, Central Los Angeles, Fontana, and Riverside in 2018. The model predicts the seasonality of nitrate (top) and OM (bottom), accurately capturing peak nitrate and OM concentrations during winter months, and their subsequent drops during the summer. This is due to increased humidity, cooler temperatures, and frequent nocturnal inversions, conditions which favor the formation of ammonium nitrate, a significant component of secondary PM_{2.5}. Summer months, in contrast, increase the volatility of nitrate, leading to relatively lower pollutant concentrations.

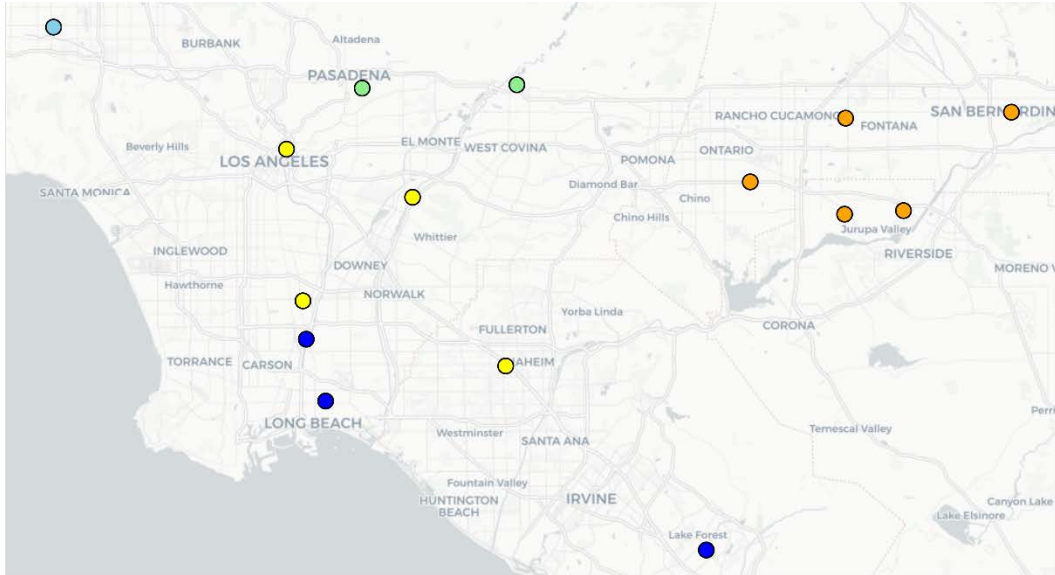

FIGURE 5-7

CMAQ performance evaluation segments the modeling domain into several sub-regions or zones. Table 5-2 lists the station locations and their assigned performance evaluation zone used to assess base-year simulation performance. Figure 5-8 maps the location of each station in the Basin. The “Urban Source” region typically has the highest emissions of PM_{2.5} and its precursors in the Basin, whereas the “Urban Receptor” region tends to experience high concentrations of secondary pollutants. Table 5-3 shows the model performance for daily PM_{2.5} in 2018 in each zone. While CMAQ underestimates PM_{2.5} mass in the San Fernando region and overestimates PM_{2.5} in over the Foothills and Urban Source regions, it shows the best model performance over the Urban Receptor region, which includes the Basin’s design site.

Future PM_{2.5} Air Quality

Annual concentrations of PM_{2.5} were simulated for the base year 2018 and two future milestone years: 2025 and 2030. Both baseline and control scenarios were analyzed for 2030, the future attainment year. The outcomes are detailed in Figure 5-9 and Table 5-4.

The CA-60 Ontario near-road monitor is the base year's design site with a value of 13.98 $\mu\text{g}/\text{m}^3$ and is predicted to maintain the highest PM_{2.5} concentrations in the basin based on the baseline simulations for 2025 and 2030 (Figure 5-9). The projected design values at that site for 2025 is 13.09 $\mu\text{g}/\text{m}^3$, failing to meet the standard of 12 $\mu\text{g}/\text{m}^3$. Similarly, Mira Loma is projected to exceed the standard in 2025, with a design value of 12.62 $\mu\text{g}/\text{m}^3$. This demonstrates that the basin requires additional time beyond 2025 to meet the annual PM_{2.5} standard.

The simulation of the 2030 baseline also indicates that Ontario CA-60 near-road and Mira Loma will still exceed the annual PM_{2.5} standard. The 2030 baseline includes emission reductions of 173 tons per day of NO_x, 58 tons per day of VOC, and 2 tons per day of PM_{2.5} with respect to 2018 base year emissions. As shown in Table 5-4, CA-60 Ontario near-road remains with the highest design value of 12.88 $\mu\text{g}/\text{m}^3$ under the 2030 baseline scenario. Additionally, the Mira Loma site is projected to exceed the 2012 annual PM_{2.5} standard with a design value of 12.48 $\mu\text{g}/\text{m}^3$. As a result, the 2030 baseline scenario falls short of demonstrating attainment, underscoring the need of additional emission reductions.

The strategy to attain the annual PM_{2.5} standard by 2030 is provided in Chapter 4 and Table 4-12, which includes co-benefits from the ozone strategy in the 2022 AQMP, as well as other proposed control measures within this PM_{2.5} Plan. However, the ozone strategy outlined in the 2022 AQMP includes 182(e)(5) measures that are permitted in the SIP/AQMP for ozone 'extreme' non-attainment status, but that are not permitted in this PM_{2.5} Plan. Thus, the 2030 attainment scenario outlined in this PM_{2.5} Plan relies on defined control measures and excludes 182(e)(5) measures from the 2022 AQMP, such as reductions from ocean-going vessels by 2030. Reflecting control measures presented in Chapter 4, emissions of NO_x, NH₃, and PM_{2.5} decrease by 17%, 4% and 3%, respectively.

Measures targeting mobile source emissions are the primary drivers of NO_x emissions reductions as over 80% of the NO_x in the Basin are from these sources. Reductions of PM_{2.5} are equally attributable to measures directed at reducing stationary and mobile source emissions. See Table 4-12 for the emission reductions of NO_x and PM_{2.5} included in the attainment scenario. Detailed descriptions of control measures and their expected reductions are also outlined in Chapter 4 and Appendix II. These reductions guarantee attainment of the 2012 federal annual PM_{2.5} standard by 2030 at all stations except CA-60 Ontario. The demonstration of attainment at the Ontario CA-60 near-road monitor requires a specific methodology that better represents the impact of on-road emissions on the near-road monitor. This novel methodology for the attainment demonstration at near-road sites is summarized in the following section.

We explored whether attaining the standard earlier would be possible with 2029 baseline emissions. Assuming a linear progress in the emission reductions resulting from the measures in this Plan between

milestone years 2028 and 2030, the approximate emissions reductions with respect to the 2029 baseline would be 24 and 0.9 tons per day of NO_x and PM_{2.5}, respectively. These reductions are from linear interpolation, not a commitment by either South Coast AQMD or CARB. Actual reductions from a rule or control measure often occur as stepwise function, not in a linear context. Our modeling system indicates that a change of one ton per day in NO_x and PM_{2.5} emissions corresponds to roughly 0.006 µg/m³ and 0.121 µg/m³ changes in the annual PM_{2.5} design value at Mira Loma. Applying this response rate and the expected emission reductions in 2029, the design value at Mira Loma is projected to be 12.15 µg/m³ in 2029. This demonstrates that the earliest attainment of the annual PM_{2.5} standard would be in 2030.

Attainment Demonstration for the Near-Road Monitor

The current design site in the basin is the near-road monitor located by CA-60 freeway in Ontario. The monitor is sited just 16 meters away from the freeway, as shown in Figure 5-10, and is heavily influenced by the emissions released from vehicles as well as resuspended particles caused by moving traffic. The Ontario CA-60 near-road monitor was established before 2015 and the monitored data became available for regulatory purposes since 2015. Since then, the station recorded the highest annual average PM_{2.5} concentration in the basin. This monitor surpassed the concentrations at the previous design site in Mira Loma, which is located approximately 12 km eastward. However, the differences in annual PM_{2.5} concentrations between Mira Loma and CA-60 near-road have narrowed since 2015, as shown in Figure 5-11. This trend can be attributed to the fact that emissions from on-road sources have decreased substantially more than all other sources in the basin (see Figure 5-12), and as a result, PM_{2.5} concentrations at near-road monitors are decreasing faster than concentrations at regional monitors that represent air quality of wider areas.

FIGURE 5-10
LOCATION OF THE ONTARIO CA-60 NEAR-ROAD MONITOR

FIGURE 5-11
ANNUAL AVERAGE PM_{2.5} CONCENTRATIONS AT THE CA-60 NEAR-ROAD AND MIRA LOMA MONITORS SINCE THE DEPLOYMENT OF THE CA-60 NEAR-ROAD MONITOR

FIGURE 5-12
TRENDS IN EMISSIONS OF DIRECT PM_{2.5} AND NO_x FROM ON-ROAD COMPARED TO THE REST OF EMISSION SOURCES FROM 2015 TO 2022

Regional chemical transport modeling is designed to calculate air quality that is representative at the grid resolution of the model. This attainment demonstration uses a model resolution of 4 km by 4 km grid, and thus, should model concentration at monitors that are representative of a similar area. Near-road sites are heavily impacted by near-road sources and thus, are not representative of the overall grid. For monitors affected by localized sources like the CA-60 Ontario near-road site, the U.S. EPA modeling guidance suggests additional modeling techniques that would support the attainment demonstration. These techniques include increasing model resolution to a finer grid or using dispersion modeling to assess the impact of primary PM_{2.5} emissions from near sources on the monitor.

Approach to Model the Effect of Near-road Sources

As the modeling guidance suggests, a regional chemical transport model may not be sufficient to represent the large gradients in PM_{2.5} concentrations at near-road monitors. As depicted in Figure 5-13, measurements at the near-road monitor observe a large contribution from near-road sources, whereas a regional model only observes those near-road impacts averaged over the entire area of the modeling grid. Thus, regional modeling is used to represent the air quality resulting from all regional sources plus the grid-average impacts of the near-road sources, whereas dispersion modeling is used to represent the near-road increment (NRI) that is the result from the monitor being next to freeway CA-60. Because of the proximity of the monitor to the freeway, it is reasonable to assume that the NRI is primarily due to direct PM_{2.5} emissions and that contribution of secondary PM_{2.5} to this NRI is negligible.

FIGURE 5-13
ILLUSTRATION OF THE NEAR-ROAD INCREMENT MODELED BY DISPERSION MODELING

The dispersion modeling is conducted using AERMOD, which is one of the official EPA dispersion models recommended for State Implementation Plan (SIP) revisions for existing sources and for New Source Review (NSR) and Prevention of Significant Deterioration (PSD) programs.¹² The modeling set-up only includes the emission sources along freeway CA-60 and its on- and off-ramps. Emission sources are grouped into 10 groups so that each category is modeled using distinctive emissions temporal and chemical profiles that can be tracked throughout the modeling. These emissions are derived from SCAG's vehicle activity dataset, which is also used in the regional modeling set-up. SCAG's dataset includes vehicle activity for 5 different vehicle classes: light and medium duty vehicles, light heavy-duty trucks, medium heavy-duty trucks, heavy heavy-duty trucks, and buses. EMFAC 2021 is used to calculate an aggregated emissions factor on a per-mile basis for these 5 groupings that includes exhaust, and tire and brake wear emissions. In addition, road dust emissions are estimated by using SCAG's vehicle activity and road information dataset and by using the road dust methodology described in Attachment H of Appendix III from the 2022 AQMP. In total, five vehicle categories and two emission processes per vehicle class for a total of ten sources of emissions are modeled using AERMOD. Detailed description of the AERMOD modeling setup is presented in Chapter 6 of Appendix II of this plan.

The estimated contributions of the near-road sources to annual PM_{2.5} at the CA60NR monitor determined by AERMOD for both 2018 and the 2030 attainment case are presented in Figure 5-14, by individual PM_{2.5} species. The annual average contribution of near-road sources at the monitor calculated using AERMOD in the 2018 base year is 3.13 µg/m³, which represents 22% of the base year design value. The contribution of near-road sources in the 2030 attainment case is projected to be 2.32 µg/m³, which corresponds to an overall 26% decrease from 2018. These results are used to determine the RRF for each PM_{2.5} species for the portion of the base year design value associated to the NRI.

¹² Air Quality Dispersion Modeling - Preferred and Recommended Models, Support Center for Regulatory Atmospheric Modeling (SCRAM), U.S. EPA, <https://www.epa.gov/scram/air-quality-dispersion-modeling-preferred-and-recommended-models>

FIGURE 5-14
AERMOD ESTIMATED CONTRIBUTIONS FROM NEAR-ROAD SOURCES FOR 2018 AND
THE 2030 ATTAINMENT CASE

The NRI is calculated using the concentration at the monitor estimated with AERMOD and the grid cell average contribution of near road sources determined by modeling PM_{2.5} concentrations with CMAQ. The near-road contribution averaged over the CMAQ grid cell where the monitor is located at is 0.15 µg/m³, which subtracted from the near-road source contribution at the monitor (3.13 µg/m³) results in an annual average NRI of 2.98 µg/m³. Alternative approaches to determine the NRI are discussed in Chapter 6 of Appendix II of this Plan. More conservative estimates for NRI lower the values down to 1.64 µg/m³.

Once the NRI is disaggregated from the regional air quality impacts contribution, the future design value can be estimated by applying two differentiated RRF values to these two components. As illustrated in Figure 5-15, the regional air quality impacts are projected using the quarterly RRF calculated from regional air quality modeling, and the NRI portion is projected using the quarterly RRF calculated using the dispersion modeling results. The resulting design value for Ontario CA-60 using this hybrid approach is 11.59 µg/m³. The future design value calculated using this hybrid approach is sensitive to the magnitude of NRI. Because emissions from on-road sources are expected to decline faster than the overall emissions in the basin, the NRI portion is projected to decline faster than the overall design value. With more conservative estimates of NRI, the projected design value calculated using this hybrid modeling tends to

be higher. Using the most conservative NRI of 1.64 $\mu\text{g}/\text{m}^3$, the resulting DV at Ontario CA-60 is projected to be 11.91 $\mu\text{g}/\text{m}^3$, still demonstrating attainment of the annual PM_{2.5} standard. A more comprehensive description of the hybrid modeling methodology and calculation of design values using this novel approach is described in Chapter 6 of Appendix II.

Unlike the conventional modeling method, which suggests that the CA-60 near-road monitor would not meet the standard under the 2030 control scenario, this hybrid approach, specifically tailored to account for the sharp PM_{2.5} concentration gradients around the freeway, indicates that the projected annual PM_{2.5} concentration will remain below 12 $\mu\text{g}/\text{m}^3$.

FIGURE 5-15
COMPARISON OF DESIGN VALUE PROJECTIONS BETWEEN THE TRADITIONAL APPROACH AND
THE HYBRID APPROACH TO ADJUST FOR NEAR-ROAD SOURCES

Spatial Projections of Annual PM_{2.5} Design Values

Figure 5-16 shows the Basin-wide spatial distribution of annual PM_{2.5} design values in the base year 2018 calculated based on interpolated design values using inverse distance-weighting of monitored DVs and model gradient-adjustment. Figures 5-17 and 5-18 show the Basin-wide spatial distribution of RRF-based annual PM_{2.5} design values for both the 2030 baseline and 2030 attainment scenario, respectively. By 2030 under baseline conditions (business-as-usual, Figure 5-17), design values exceeding the 12 µg/m³ federal standard are confined to a small region surrounding the Mira Loma and Ontario CA-60 monitoring stations in the northwestern boundary of Riverside and San Bernardino Counties. With the PM_{2.5} precursors reductions associated with the control measures proposed in this PM_{2.5} plan (Figure 5-18), the Basin is expected to meet the federal PM_{2.5} standard throughout the Basin.

FIGURE 5-18
2030 ATTAINMENT ANNUAL PM_{2.5} RRF DESIGN VALUE CONCENTRATIONS.

Summary and Conclusions

Figure 5-19 presents the 2018 observed and 2030 projected future design values for annual PM_{2.5}. Mira Loma and Ontario CA-60 near-road stations are expected to exceed the annual PM_{2.5} standard under the 2030 baseline scenario. This 2030 baseline scenario projects emissions based on the rules that are in place by the cutoff date of this plan and represents a ‘business-as-usual’ projection. The emissions reductions beyond the baseline emission levels proposed in this Plan would enable the Basin to meet the 2012 annual PM_{2.5} standard. Table 5-5 summarizes the design values at the Mira Loma and Ontario CA-60 monitors, the two stations with the highest PM_{2.5} annual levels in the 2018 base year and the 2030 attainment year. Based on the design values for 2030 and model sensitivity analyses, the design value for 2029 at Mira Loma is projected to be above 12.04 µg/m³, exceeding the 2012 annual PM_{2.5} standard. Therefore, the earliest that the PM_{2.5} standard can be met in the South Coast Air Basin is projected to be 2030.

CHAPTER 6

Federal Clean Air Act Requirements

- Due to unforeseen challenges such as adverse meteorology and high levels of PM_{2.5} recorded at near road monitors, it is impractical to attain the 2012 annual PM_{2.5} standard by the statutory “serious” area attainment date, December 31, 2025.
- This Plan requests an extension of the attainment date to December 31, 2030, as allowed by the Clean Air Act Section 188(e). With the control strategy proposed in this Plan, the South Coast Air Basin is expected to attain the 2012 annual PM_{2.5} standard by 2030.
- The PM_{2.5} Plan complies with SIP planning requirements including, but not limited to, reasonable further progress, quantitative milestones, a comprehensive emissions inventory, the implementation of best available control measures and most stringent measures, control strategies, contingency measures, transportation conformity, motor vehicle emissions budget, and new source review.

Other Federal Clean Air Act Requirements

This Plan addresses all “serious” PM2.5 nonattainment area Clean Air Act (CAA) planning requirements as shown in Table 6-1. Chapters 3 to 5 of this Plan fulfill the requirements related to the updated emissions inventory, control strategy, and attainment demonstration. This chapter addresses other CAA requirements.

TABLE 6-1
FEDERAL CLEAN AIR ACT REQUIREMENTS FOR THE 2012 PM2.5 NAAQS

Requirement	CAA Section	Definition	Location in Plan
Emissions Inventory	172(c)(3)	A comprehensive, accurate, current inventory of actual emissions from all sources of the relevant pollutant or pollutants.	Chapter 3
BACM/BACT	189(b)(1)(B)	Provisions to assure that the Best Available Control Measures (BACM) for the control of PM2.5 shall be implemented no later than 4 years after the date the area is reclassified as a “serious” nonattainment area. BACM includes Best Available Control Technology (BACT).	Chapter 4, Appendix III, Appendix IV
Attainment Demonstration	189(b)(1)(A), 188(e)	Attainment date shall be as expeditiously as practicable but no later than the end of the fifteenth calendar year after designation as nonattainment.	Chapter 5
Extension of Attainment Date for Serious Areas	188(e)	Demonstrations that 1) attainment by the statutory “serious” area attainment date is impracticable, 2) the State has complied with all requirements and commitments pertaining to the area in the SIP, and 3) the State demonstrates that the Plan includes the most <u>stringent</u> measures (MSM) feasible for the area.	Chapter 6, Appendix III
Reasonable Further Progress	172(c)(2)	Plan provisions shall require reasonable <u>further</u> progress (RFP).	Chapter 6
Transportation	176(c)	Plan provisions addressing transportation	Chapter 6

Requirement	CAA Section	Definition	Location in Plan
Conformity		conformity, including motor vehicle emissions budgets for RFP milestone years and the attainment year.	
Quantitative Milestones	189(c)	The Plan shall contain quantitative milestones which are to be achieved every three years until the area is redesignated attainment and which demonstrate reasonable further progress toward attainment by the applicable attainment date.	Chapter 6
Nonattainment New Source Review	189(a)(1)(A), 189(b)(3), 189(e)	A permit program requiring permits for the construction and operation of new and modified major stationary sources of PM. Control requirements applicable to major stationary sources of PM _{2.5} shall also apply to major stationary sources of PM _{2.5} precursors.	Chapter 6
Contingency Measures	172(c)(9)	Fully adopted rules or control measures that are ready to be implemented, should U.S. EPA issue a final rule that the Basin failed to meet a regulatory requirement necessitating implementation of a contingency measure. Contingency measures must take effect without significant additional action by the state or local agency or by U.S. EPA.	Chapter 6, Appendix V

Request for Extension of Attainment Date to 2030

Through this plan, South Coast AQMD is formally requesting an extension of the attainment deadline from December 31, 2025 to December 31, 2030 as allowed under CAA Section 188(e). U.S. EPA requires that additional elements accompany the attainment deadline extension request in order to consider it. First, an impracticability demonstration must be provided, showing that the area cannot practicably attain by the end of the tenth calendar year following designation of the area. Second, the State Implementation Plan (SIP) must provide for the implementation of ~~Most Stringent Measures (MSM)~~. Finally, a demonstration of compliance with all requirements and commitments in the applicable SIP must be included.

Impracticability Demonstration

The 2016 AQMP included a strategy to attain the 2012 annual PM_{2.5} standard by the 2025 attainment year. The strategy primarily relied on co-benefits from the measures to attain the 1997 8-hour ozone standard by 2023 and the 2008 8-hour ozone standard by 2031. Since the submittal of the 2016 AQMP, South Coast AQMD has implemented control measures and achieved emission reductions reflected in the 2016 AQMP attainment demonstration. However, progress in achieving the needed emission reductions was hampered by a variety of circumstances. These include a lack of action at the federal level for sources such as aircraft, ships, trains, interstate trucks, and offroad equipment. Such sources are the dominant source of nitrogen oxides (NO_x) emissions in the region and are subject to federal regulatory authority. Additionally, the region experienced unforeseen challenges including unfavorable meteorology, wildfires, increases in emissions in the goods movement sector during the COVID-19 pandemic, and the addition of the near-road monitors. All of these factors resulted in higher than expected PM_{2.5} concentrations.

Prior to the submittal of the 2016 AQMP, U.S. EPA established a requirement to monitor PM_{2.5} levels at near-road locations. Two near-road monitoring stations along the Interstate 710 (I-710) in Long Beach and the California State Route 60 (CA-60) in Ontario began PM_{2.5} measurements in 2015. At the time of 2016 AQMP adoption, neither of these monitors had sufficient data to be considered in the attainment demonstration. By January 1, 2020, however, these monitors had accumulated sufficient data to be considered in attainment demonstrations and the CA-60 monitor was measuring the highest PM_{2.5} levels in the Basin. The 2022 design value at the CA-60 monitor was 13.7 µg/m³.

U.S. EPA did not act on the submitted plan for a few years and, by the time the South Coast Air Basin was reclassified to “serious” nonattainment in 2020, U.S. EPA stated that near-road monitors must now be included in a supplemental attainment demonstration. South Coast AQMD subsequently determined that demonstrating attainment by 2025, especially at the CA-60 monitor, was impractical.

Currently, model-predicted design values for 2025, the statutory “serious” area attainment year, are well above 12.0 µg/m³ at multiple monitors (see Chapter 5, Table 5-4). This scenario reflects baseline emissions with adopted regulations and programs by South Coast AQMD and CARB. Another scenario, presented in Chapter 5, is also considered. In this scenario, emission reductions from recently adopted regulations not yet in the baseline are considered. Even with those additional reductions, attainment by 2025 is impractical. It is impractical and infeasible to implement additional reductions beyond already adopted regulations by December 31, 2024, given the amount of time needed to adopt and implement rules and regulations. The control strategy also requires that South Coast AQMD undertake multiple rulemakings, each with its own extensive public process. The proposed attainment year, 2030, reflects the challenges and complexities associated with this plan while balancing expeditious attainment and the time needed to adopt a SIP revision, develop rules, and achieve emission reductions.

Implementation of MSM

Appendix III presents a comprehensive BACM demonstration which also serves to demonstrate MSM. U.S.

EPA interprets MSM to mean the maximum degree of emission reduction that has been required or achieved from a source or source category in any other attainment plans or in practice in any other states and that can feasibly be implemented in the area seeking the extension. In Appendix III, potential control measures identified via MSM evaluation are assessed for technological and economic feasibility and incorporated as control measures if they are feasible. If potential MSM are rejected as infeasible, a reasoned justification is provided.

Compliance With the Applicable SIP

The final element that is required to accompany an attainment date extension request is a demonstration of compliance with commitments made in the applicable SIP. In this case, the applicable SIP is the “moderate” area plan for the 2012 annual PM_{2.5} standard which was submitted as part of the 2016 AQMP. U.S. EPA approved all but the contingency measure element of the 2016 AQMP as meeting applicable “moderate” area requirements.¹ With respect to the contingency measure element, U.S. EPA granted conditional approval based on South Coast AQMD’s commitment to adopt and submit a contingency measure for approval. In response, Rule 445 was amended twice in 2020 to add PM_{2.5} and ozone contingency provisions. Rule 445 was subsequently approved by U.S. EPA, excluding paragraph (g) (Ozone Contingency Measures) and paragraph (k) (Penalties), as fulfilling the commitment to adopt a contingency measure for PM_{2.5}.²

With respect to the Reasonably Available Control Measures (RACM)/Reasonably Available Control Technology (RACT) analysis, the “moderate” area plan in the 2016 AQMP concluded that South Coast AQMD’s existing rules were generally equivalent to, or more stringent than, those developed by other air districts. Thus, there were no control measures identified as RACM/RACT and no commitments were made in the “moderate” area plan. ~~There were, however, four control measures in the 2016 AQMP identified as additional reasonable measures with full or partial implementation by 2020 (see Table 6-2). U.S. EPA approved these additional reasonable measures including CMB-02, CMB-03, BCM-04, and BCM-10.~~³

TABLE 6-2
SUMMARY OF ADDITIONAL REASONABLE MEASURES FOR
ANNUAL PM2.5 IN THE 2016 AQMP

CM Number	Title	Adoption	Implementation Period	Commitment Satisfied?
CMB-02	Emission Reductions from Replacement with Zero or Near-Zero NOx Appliances in Commercial and Residential Applications [NOx]	2018	2020-2031	Yes, Rule 1111
CMB-03	Emission Reductions from Non-Refinery Flares [NOx, VOC]	2018	2020	Yes, Rule 1118.1
BCM-04	Emission Reductions from Manure Management Strategies [NH3]	2019	2020	Yes, substitute reductions achieved
BCM-10	Emission Reductions from Greenwaste Composting [NH3]	2019	2020	Yes, substitute reductions achieved

As shown in Table 6-2, the 2016 AQMP also included a number of control measures (CMs) to reduce PM2.5 and PM2.5 precursor emissions. However, these control measures were associated with “serious” area plan commitments. Since the “serious” area plan was withdrawn, South Coast AQMD is not required to demonstrate compliance with those commitments.

TABLE 6-2*
SUMMARY OF CONTROL MEASURES IN THE WITHDRAWN “SERIOUS” AREA PLAN FOR
ANNUAL PM_{2.5} IN THE 2016 AQMP

* Reproduced with slight modifications from Table 4-7 in the 2016 AQMP.

South Coast AQMD evaluated its commitments included in the withdrawn “serious” area plan to track progress in PM_{2.5} and its precursors’ reductions. fulfilled CMB-02 and CMB-03 commitments through amendments to Rule 1111 and adoption of Rule 1118.1, respectively, whileSpecifically, the following discussion surrounds -the 2016 AQMP control measures BCM-04 and BCM-10, which have not yet been

adopted as rules. However, the quantified reductions from these measures are less than 0.5 percent of all ammonia emissions. The air quality benefit of the surplus nitrogen oxides (NO_x) and PM reductions achieved in 2022, discussed in detail later, is expected to greatly exceed the potential benefit of the relatively small ammonia reductions from BCM-04 and BCM-10. Additionally, updated analysis conducted for the PM_{2.5} Plan shows that ammonia emissions from livestock are considerably lower than those assumed in the 2016 AQMP. Total ammonia emissions for dairy cattle, poultry layers, and swine are 1.2 tons per day lower than the projected emissions for the 2025 attainment year in the 2016 AQMP (see Table 6-3). Therefore, the reductions achieved in practice far exceed the reductions sought by BCM-04 and BCM-10.

TABLE 6-3
COMPARISON OF 2030 LIVESTOCK AMMONIA EMISSIONS IN THE 2016 AND 2022 AQMPs

CES	Category Description	NH ₃ emissions (tpd)	
		2016 AQMP	2022 AQMP
89516	LIVESTOCK HUSBANDRY - DAIRY CATTLE	4.55	5.08
89557	LIVESTOCK HUSBANDRY - LAYERS	1.92	0.28
89573	LIVESTOCK HUSBANDRY - SWINE	0.15	0.02
Total		6.62	5.38

Implementation of certain control measures not only depends on South Coast AQMD, but also on state actions. South Coast AQMD determined that state legislation has achieved many of the same objectives as BCM-10 and this control measure has therefore been implemented statewide. The BCM-10 proposed control methods included potential emission reductions to be achieved through increased diversion of foodwaste from landfills to anaerobic digestion (AD), along with pollution control technology, and restricted direct land application (DLA) of chipped and ground uncomposted greenwaste.

BCM-10 was tied with implementation of AB 341 (Chesbro, Chapter 476, Statutes of 2011) and AB 1826 (Chesbro, Chapter 727, Statutes of 2014). AB 341 required mandatory commercial recycling, composting, or source reduction of 75 percent by 2020. AB 1826 introduced organic waste recycling requirements for businesses starting April 1, 2016, depending on the amount of waste they generate per week. For the purpose of AB 1826, organics were meant to include foodwaste, greenwaste, landscape/pruning waste, nonhazardous wood, and food-soiled paper waste mixed with foodwaste. Organics accounted for 34 percent of California's disposed waste stream in 2014.⁴ While AB 341 established a 75 percent recycling target by 2020, the actual statewide recycling rate (through source reduction, recycling, and composting) was only 42 percent in 2020.⁵ AB 1826 had phased-in requirements for businesses over time. In September

⁴ <https://calrecycle.ca.gov/Recycle/Commercial/Organics/MandatoryCommercialOrganicsRecycling-CalRecycle-Home-Page>

⁵ [CalRecycle, State of Disposal and Recycling in California for Calendar Year 2020. 2021: https://www2.calrecycle.ca.gov/Publications/Download/1754](https://www2.calrecycle.ca.gov/Publications/Download/1754)

2020, CalRecycle reduced the threshold to 2 cubic yards of solid waste (the total of trash, recycling, and organics) generated by covered businesses.

More recently, other legislation has been enacted to decrease emissions from landfills. SB 1383 (Lara, Chapter 395, Statutes of 2016) is the most significant landfill waste reduction mandate adopted in California. Its goal is to reduce organic waste landfill disposal by 50 percent from 2014 levels by 2020 and 75 percent by 2025. However, implementation of SB 1383 has faced challenges. In 2020, organic waste in landfills increased by a million tons above the 2014 baseline.⁶ The reasons for this increase may include: 1) residential organic waste separation and collection were not fully in effect until January 2022, and 2) more residential foodwaste was generated because of COVID-19. Due to restaurants shifting from dine-in to take-out and customers buying groceries in bulk, the generation of foodwaste increased as did the associated packaging waste.⁷

Since January 2022, approximately 72 percent of California communities have implemented residential organic waste collection, while 126 out of 615 jurisdictions (~20 percent) have requested more time to reach compliance.⁸ Rural and low population jurisdictions have waivers and exemptions from organic waste collection requirements. Data on the effectiveness of the residential organic waste collection program in achieving emission reductions is lacking.

In BCM-10, AD was one of the proposed control methods to handle the increased diversion of organic waste (mostly foodwaste) from landfills, resulting in emission reductions. State laws have been enacted to achieve the intent of BCM-10 since the adoption of the 2016 AQMP. While implementation of those laws has not proceeded as envisioned, the legal requirement to increase diversion of waste from landfills exists. Therefore, staff concludes that state actions have fulfilled the BCM-10 commitment.

Quantitative milestones provide another means to demonstrate continued compliance with the applicable SIP. CAA Section 189(c) requires that quantitative milestones must be achieved every 3 years until the area is redesignated attainment which demonstrate ~~Reasonable Further Progress (RFP)~~ toward attainment. South Coast AQMD submitted the 2022 Quantitative Milestone Report (QMR) to U.S. EPA demonstrating continued compliance with all applicable commitments for the 2012 annual PM_{2.5} standard.⁹ The 2016 AQMP projected that 7 tpd of surplus NO_x reductions would be needed to meet the 2022 RFP target, while all other pollutants would meet RFP based on baseline measures. Total surplus reductions were determined to be 15.90 tpd NO_x and 0.51 tpd PM_{2.5}, significantly exceeding the 7 tpd of NO_x reductions needed for RFP.

A significant portion of the reductions came from mobile source incentive measures. The 2016 AQMP included MOB-14 – Emission Reductions from Incentive Programs and provided a mechanism to ensure

⁶ Little Hoover Commission, Reducing California's Landfill Methane Emissions: SB 1383 Implementation, Report #274, June 2023: <https://lhc.ca.gov/sites/lhc.ca.gov/files/Reports/274/Report%20274.pdf>

⁹ Submitted to U.S. EPA via CARB on June 7, 2023

that emission reductions were SIP creditable. The incentive programs include the Carl Moyer Program, Proposition 1B – Air Quality Improvement Fund, Lower-Emission School Bus Program (LESBP), and the Community Air Protection Program (CAPP). The Carl Moyer Program funds projects that reduce NO_x, volatile organic compound (VOC) and PM caused by the combustion of diesel and gasoline in on-road vehicles and off-road engines. The program also funds after-treatment devices such as diesel oxidation catalysts and PM filters. The emission reductions from Proposition 1B are the result of the deployment of cleaner locomotives and heavy-duty trucks. Since 2018, LESBP has funded the replacement of 201 school buses with newer, cleaner models and CAPP incentives have resulted in emission reductions from locomotives, heavy-duty trucks, cargo handling equipment, harbor craft, and other sources that impact disadvantaged communities. Table 6-4 summarizes the emission reductions from these incentive programs.

**TABLE 6-4
SURPLUS NOX AND PM2.5 REDUCTIONS IN 2022 FROM
MOBILE SOURCE INCENTIVE PROGRAMS**

Program	Source Category	NO _x (tpd)	PM2.5 (tpd)
Carl Moyer	Metrolink ¹⁰	3.00	Not Quantified
	Harbor Craft	3.32	0.128
	Off-road	3.80	0.139
	On-road	0.17	0.003
	Locomotives	0.11	0.002
Prop 1B	Freight Locomotives	0.61	0.023
	On-road HD Trucks	0.38	0.000
LESBP	School Buses	0.10	0.005
CAPP	Harbor Craft	0.27	0.012
	Off-road	1.41	0.041
	On-road	0.14	0.000
	Locomotives	0.67	0.023
	Total	13.99	0.377

¹⁰ Funded with Carl Moyer and other programs. Since February 2013, South Coast AQMD awarded Metrolink a total of \$101.85 million for the replacement of 37 Tier 0 & Tier 2 locomotives with Tier 4 locomotives and the new purchase of three Tier 4 locomotives. As of April 2021, 39 Tier 4 locomotives had been delivered to Metrolink and delivery of a final Tier 4 locomotive was expected by June 2021. Beginning in fiscal year 2022, Metrolink

The 2022 QMR quantified additional reductions resulting from the unused portion of the general conformity set-aside account. Pursuant to Clean Air Act Section 176(c) (42 U.S.C. 7506) and the U.S. EPA's implementing regulations (40 CFR Part 93, Subpart B and 40 CFR Part 51, Subpart W), general conformity is required for NAAQS nonattainment and maintenance areas. The intent of general conformity is to prevent the air quality impacts of a proposed federal action, under Title 23 U.S.C., from causing or contributing to new violations of the air quality standards, exacerbating existing violations, or interfering with the purpose of the applicable implementation plan.

In order to streamline a conformity evaluation process, SIP set-aside accounts were allocated in the 2016 AQMP. The revised set-aside account to accommodate projects subject to general conformity included a balance of: 2.0 tpd of NO_x and 0.5 tpd of VOC each year from 2017 to 2030, and 0.5 tpd of NO_x and 0.2 tpd of VOC in 2031. Emissions from general conformity projects are tracked by South Coast AQMD and debited from the account on a first-come-first-serve basis. In 2022, the set-aside account had a remaining balance of 1.15 tpd NO_x and 0.32 tpd VOC since approved projects had not consumed the entire allocation.

A summary of the overall NO_x reductions quantified as part of the 2022 QMR is presented in Table 6-5. In addition to the incentive measures and general conformity set-aside account, the Regional Clean Air Incentives Market (RECLAIM) shutdown credit, Rule 445, and Rule 1179.1 reductions are considered.

The RECLAIM shutdown incorporates reductions from the decommissioning of a coke calciner in 2022 by Marathon Petroleum Corporation. The reductions from Rule 445 - Wood Burning Devices - stem from the June 2020 amendment which established PM_{2.5} contingency provisions that would be automatically triggered in the event that the U.S. EPA determines that the Basin failed to meet any RFP requirement, meet any quantitative milestone, submit a quantitative milestone report, or attain applicable PM_{2.5} NAAQS by the attainment date. The amendment also expanded the curtailment to the entire Basin instead of using a source receptor area approach. The South coast Air Basin failed to attain the 2006 24-hour PM_{2.5} standard by the statutory attainment date, December 31, 2019, which triggered a contingency measure in Rule 445 and lowered the curtailment threshold to 29 µg/m³ in 2020.¹¹ Overall, the amendment resulted in a total of 0.13 tpd of PM_{2.5} reductions. Finally, Rule 1179.1 - Emission Reductions from Combustion Equipment at Publicly Owned Treatment Works Facilities - was adopted in October 2020 and established NO_x emission limits for boilers, process heaters and engines burning digester gas or those units capable of burning digester and natural gas.

anticipated operating 40 trainsets serviced by a fleet of 48 to 52 locomotives. The emission reductions from the Tier 4 conversions and the purchase of the new Tier 4 locomotives, which are surplus to the 2016 AQMP inventory, are estimated to be 3 tpd in 2022

¹¹ Finding of Failure To Attain the 2006 24-Hour Fine Particulate Matter Standards; California; Los Angeles- South Coast Air Basin, 85 Fed. Reg. 57733 (Sept. 16, 2020)

TABLE 6-5
SURPLUS REDUCTIONS IN 2022 BASED ON REGULATIONS AND INCENTIVES

Regulation/Incentive	Surplus NO _x Reduction in 2022 (tpd)	Surplus PM _{2.5} Reduction in 2022 (tpd)
Rule 445	Not Quantified	0.13
Rule 1179.1	0.05	Not Quantified
RECLAIM Shutdown Credit (Rule 1109.1)	0.71	Not Quantified
Mobile Source Incentive Programs	13.99	0.38
General Conformity Set-Aside Credit	1.15	N/A
Total	15.90	0.51

In summary, South Coast AQMD determined that, although BCM-04 and BCM-10 were not adopted as rules, substitute reductions were achieved. ~~all annual PM_{2.5} “moderate” area plan commitments have been fulfilled. The additional reasonable measures identified in the 2016 AQMP have either been implemented or substitute reductions have been achieved.~~ These reductions exceed the level of reductions committed by the measures in the withdrawn “serious” area plan. BCM-04 and BCM-10 have been incorporated into the control strategy of this plan (as BCM-08 and BCM-10) and South Coast AQMD commits to adopt the measures to satisfy MSM requirements.

~~In the 2016 AQMP, South Coast AQMD committed to achieve emission reductions in aggregate to accommodate necessary changes during rulemaking, during which emission reduction commitments of individual control measures are adjusted to reflect stakeholder’s needs, technological maturity, commercial availability and other economic needs. The reductions quantified as part of the 2022 QMR, which are surplus to the 2016 AQMP baseline and count towards the aggregate reduction commitment, exceed the level of reductions needed to demonstrate RFP. Therefore, South Coast AQMD concludes that commitments to adopt control measures and meet RFP targets have been achieved.~~

Reasonable Further Progress and Quantitative Milestones

Reasonable Further Progress

The CAA requires that SIPs for most nonattainment areas demonstrate Reasonable Further Progress (RFP) towards attainment through emission reductions phased in from the base year until the attainment date. Per CAA Section 171(1), RFP is defined as:

“such annual incremental reductions in emissions of the relevant air pollutant as are required by this part or may reasonably be required by the Administrator for the purpose of ensuring attainment of the applicable national ambient air quality standard by the

applicable date.”

Emission reductions required under an RFP plan for PM_{2.5} are directly emitted PM_{2.5} and applicable precursors. Appendix VI of this Plan presents a precursor demonstration to exclude VOCs and sulfur oxides (SO_x) from certain planning requirements including the RFP demonstration. Therefore, this RFP demonstration focuses on NO_x, direct PM_{2.5}, and ammonia (NH₃) as the pollutants with a significant impact on PM_{2.5} levels.

To determine RFP for the attainment date, U.S. EPA guidance states that the plan should rely only on emission reductions achieved from sources within the nonattainment area. Section 172(c)(2) of the CAA requires that attainment plans show ongoing annual incremental emission reductions toward attainment, which is commonly expressed in terms of target emission levels to be achieved by certain interim milestone years.

For PM_{2.5} nonattainment areas, in addition to the RFP requirements, CAA Section 189(c)(1) requires states to achieve quantitative milestones, which are designed to track RFP to ensure expeditious attainment. U.S. EPA requires that all “serious” area PM_{2.5} attainment plans define appropriate quantitative milestones to be achieved 7.5 years from the original designation of the area and every 3 years thereafter until the area is re-designated as attainment.¹² The South Coast Air Basin was originally designated nonattainment for the 2012 annual PM_{2.5} NAAQS effective April 15, 2015.¹³ Therefore, the first “serious” area quantitative milestone occurred on October 15, 2022. The 2022 Quantitative Milestone Report was submitted to U.S. EPA to address compliance with this milestone.

U.S. EPA requires that RFP plans contain projected emissions for each calendar year in which quantitative milestones must be met. Since the first “serious” area quantitative milestone is in the past (October 15, 2022), the first quantitative and RFP milestone year considered in this plan is 2025. The quantitative milestones recur every 3 years and continue through 2031, the post-attainment milestone year.

As described in Chapter 3 – Base-Year and Future Emissions, the base year of this Plan is 2018, which also serves as the base year for the purposes of tracking RFP. Alignment of the RFP and modeling base year is clarified in U.S. EPA’s implementation rule for PM_{2.5} NAAQS.¹⁴

“Because the statute does not clearly establish the applicable baseline year from which to begin calculating annual emissions reductions for purposes of demonstrating RFP, the EPA is finalizing a requirement that states use the same year as the base year inventory used for developing the control strategy and associated air quality modeling demonstrating that the area will attain expeditiously.”

¹² CFR §51.1013(a)(2)(i)

¹³ Air Quality Designations for the 2012 Primary Annual Fine Particle (PM_{2.5}) National Ambient Air Quality Standards (NAAQS), 80 Fed. Reg. 2206 (Jan. 15, 2015)

¹⁴ Fine Particulate Matter National Ambient Air Quality Standards: State Implementation Plan Requirements, 81 Fed. Reg. 58009 (Aug. 24, 2016)

U.S. EPA requires that all SIPs contain RFP projected emissions and that those emissions demonstrate either: (i) Generally linear progress toward the projected attainment date; or (ii) stepwise progress toward the projected attainment date with proper justification.¹⁵ This analysis demonstrates generally linear RFP for NOx and direct PM2.5 and stepwise RFP for ammonia.

Stepwise RFP Justification

The RFP demonstrations for NOx and PM2.5 were conducted following the generally linear approach, while RFP for ammonia was demonstrated using the stepwise approach. This is due to the nature of ammonia emissions in the Basin, technologies anticipated to bring ammonia reductions, and the timeline to develop and implement rules to achieve reductions.

Attainment of the 2012 annual PM2.5 NAAQS requires NOx and PM2.5 emissions reductions of 54 percent and 6 percent, respectively, from 2018 to 2030. While portions of the needed reductions come from continued implementation of already adopted rules and regulations, new reductions from the proposed control measures are necessary for attainment. In Chapter 4, Tables 4-4 and 4-5 present South Coast AQMD's commitment to adopt and implement the proposed control measures. CARB's commitments are provided in Tables 4-6 and 4-11, which includes adoption and implementation dates for each measure. The adoption and implementation dates are as expeditious as possible and reflect best estimates of the time required to develop and implement each proposed measure. Table 4-9 summarizes emission reductions in the South Coast Air Basin in 2030 from CARB programs. In Table 4-9, the reductions estimated from the remaining 2016 State SIP Strategy and future measures identified in the 2022 State SIP Strategy are described as the "potential CARB aggregate emissions reductions commitment" until the CARB Board adopts the aggregate emissions reductions commitment for the year 2030. These reductions are needed to demonstrate RFP.

In addition, the nature of ammonia emissions needs to be considered. The South Coast Air Basin is a highly urbanized area with limited agricultural activities and dairy operations. The majority of ammonia emissions come from area sources such as humans and pets in the Basin. Other large sources include on-road vehicles, industrial processes, and farming. Area source emissions are expected to grow in the future due to increases in the population of humans and pets. While the ammonia emissions from mobile or stationary point sources can be controlled by transitioning to zero emissions, ammonia from humans and pets cannot be controlled with current technology. Although there are limited ammonia controls proposed in control measures BCM-08 through BCM-11, the majority of ammonia reductions are anticipated from the deployment of zero emission vehicles. This contrasts with the widespread availability of control technologies targeting NOx and PM2.5 from combustion sources. For NOx, Selective Catalytic Reduction (SCR) and low-NOx burners are available and, for PM2.5, Diesel Particle Filters are available for certain applications. Such controls are already required by adopted regulations and will continue to lower NOx and PM2.5 emissions to meet generally linear progress toward attainment. However, such NOx and PM2.5 control technologies often do not reduce ammonia concurrently and transition to zero emissions

¹⁵ CFR § 51.1012(a)(4)

technologies is often the only pathway to achieve significant amount of ammonia reductions. Although the deployment of zero emission technologies is complex and requires more time to implement, ammonia emissions will be sufficiently controlled to attain the 2012 annual PM_{2.5} standard in 2030.

In summary, it is necessary to rely on a stepwise RFP demonstration for ammonia. Generally linear progress is not feasible due to the type of control technologies relied on for attainment, and time required to develop and implement rules.

Adoption Dates

The committed adoption dates in Table 4-4, Table 4-5, and Table 4-6 are based on the best estimate of the amount of time required to develop a measure. Time spent in this developmental phase is influenced by the level of interest from stakeholders and conflicts of interest, if any, among stakeholders. Maturity of technology, market capacity for at-scale deployment, infrastructure to support the new technology, and cost effectiveness determine the timeline to develop a proposed control measure to a rule/regulation. In addition, once the proposed measure has been developed, it must be adopted through a public process, which entails procedural requirements with their own timing.

Implementation Dates

The committed implementation dates in Table 4-4, Table 4-5, and Table 4-6 are based on the best estimate of the amount of time required for measure adoption and procedural elements as well as the implementation phase. For example, CARB regulations, once adopted, undergo a prescribed review process by the State Office of Administrative Law (OAL) to ensure compliance with California's Administrative Procedure Act before the measure can be codified in the California Code of Regulations. The effective date of an OAL-approved regulation can be a year or more from the date of CARB adoption. Following development and adoption, in all cases, the implementation schedule of a measure must account for the time needed by the affected entities to comply with the requirements in the measure. This includes planning for, and investing in, the resources to implement the required controls—to change, buy, or install new technology, if applicable. Specific challenges related to the timing of implementation of innovative South Coast AQMD and CARB measures are described in further detail below.

South Coast AQMD Stationary Source Measures

As outlined in Table 4-4, South Coast AQMD has committed to adopt stationary source control measures beginning in 2024, and not later than 2027. Implementation is set to begin as expeditiously as possible for each measure. For example, for BCM-10 - Emission Reductions from Direct Land Application of Chipped and Ground Uncomposted Greenwaste, is scheduled to adopt in 2026 but will be implemented starting in 2030. This is to allow composting facilities sufficient lead time to expand their operations to accommodate the increased demand for greenwaste composting.

Further understanding of the applicability of control technologies, the cost-effectiveness of controls, and the socioeconomic impacts of potential regulations are necessary before regulations can be adopted. The

market availability of control equipment capable of reducing emissions further than the already stringent limits required by South Coast AQMD's technology-forcing rules is an additional consideration in implementing new regulatory requirements.

Time after rule adoption will be necessary for manufacturers and vendors to make available compliant equipment, and for facility operators to source, purchase, and install new units or compliant retrofit equipment. Dependent on the source category, construction of controls may include engineering, site preparation and infrastructure upgrades, unit installation, and operator training on proper operation. Potential control technologies have significant costs to affected facilities, and these operations will also require time to plan for these investments. Based on these challenges, rule implementation is not expected to be feasible prior to the implementation date listed in Table 4-4.

Considering the factors mentioned earlier, the emission reductions resulting from the proposed control measures are projected to materialize around 2030 rather than in the immediate future. This necessitates a stepwise RFP demonstration for ammonia. The expeditious implementation of some measures, where feasible, may result in emission reductions that occur before 2030. South Coast AQMD commits to demonstrate and discuss any early emission reductions achieved in Quantitative Milestone Reports.

Zero Emission Mobile Source Measures

Mobile sources are responsible for approximately 25 percent of the NH₃ emissions in the South Coast; NH₃ can be emitted as a byproduct during the use of control technologies designed to lower the emissions of NO_x, the dominant precursor of both ozone and PM_{2.5} pollution. In engines fueled by Compressed Natural Gas (CNG), NH₃ is formed as a byproduct of a three-way catalyst that converts NO_x to nitrogen (N₂). In diesel engines, Selective Catalytic Reduction controls use NH₃ as a catalyst to convert NO_x to N₂ and water. Unreacted NH₃ can be emitted as part of in this process, referred to as an ammonia slip.

CARB programs that drive mobile sources to zero-emission vehicles and engines will provide ammonia emission reduction benefits in 2030 in the South Coast, in addition to significant NO_x and PM_{2.5} reductions; these programs include adopted regulations such as the Advanced Clean Cars, Advanced Clean Trucks, Advanced Clean Fleets, and the Transport Refrigeration Unit (Part I) Regulations, and proposed measures such as the Zero-Emissions Truck Measure, Transport Refrigeration Unit (Part II) Regulation, and Cargo Handling Equipment Amendments. CARB's adoption and implementation schedules are as expeditious as possible, but like many stationary source control measures, sufficient time is needed for both regulatory development and for development, manufacture, and purchase of control technologies prior to emissions reductions being achieved from these programs. Based on these challenges, rule implementation is not expected to be feasible prior to the implementation date listed in Table 4-8. Considering all of the factors mentioned, the majority of emission reductions resulting from the proposed control measures are projected to be achieved by 2030 rather than in the near-term years.

RFP Demonstration

This analysis demonstrates generally linear RFP for NO_x and direct PM_{2.5} emissions and stepwise RFP for ammonia emissions. Table 6-6 presents the baseline emissions of NO_x, direct PM_{2.5}, and ammonia including line item adjustments reflecting adopted regulations for the RFP milestone years. The regulations included in the line item adjustments are provided in Table 6-7. RFP is demonstrated using reductions from three categories: adopted regulations already reflected in the baseline emissions, regulations adopted since the development of the 2022 AQMP, and control measures proposed in this Plan. The second category includes South Coast AQMD's rules adopted during November 2020 to September 2023 and CARB's regulations adopted in 2022 and afterwards. The projected emissions account for all of these reductions. However, in some years, the RFP target is higher than the projected emissions. This is because the projected emissions are below the level needed to demonstrate linear progress. RFP is expected to be met for all milestone and attainment years as presented in detail for each pollutant in subsequent sections. The 2031 post-attainment year target is assumed to have same amount of reductions as the attainment scenario. However, in reality, 2031 emissions are expected to be below the RFP target levels due to continued implementation of the control strategies required to meet the 2008 and 2015 ozone NAAQS by 2031 and 2037, respectively.

**TABLE 6-6
REASONABLE FURTHER PROGRESS CALCULATIONS FOR MILESTONE YEARS**

	Pollutant	2018	2025	2028	2030	2031

Table 6-8 summarizes the total reductions needed from the 2018 baseline emissions inventory that must be achieved to reach attainment in 2030.

TABLE 6-8
TOTAL REDUCTIONS NEEDED FOR ATTAINMENT (TPD)

Pollutant	2018 Base Year Emissions	2030 Attainment Scenario Emissions	Total Reductions Needed
NO_x	383.02	175.37	207.65
PM_{2.5}	56.04	52.68	3.36
NH₃	74.54	76.11	-1.57*

*Negative reductions reflect increase in emissions from 2018 to 2030

NO_x

NO_x emissions are expected to decrease in a generally linear fashion from the base year to the attainment scenario, as shown in Figure 6-1. The NO_x emission reductions anticipated from the baseline reductions and line item adjustments are sufficient to meet or exceed the RFP targets. Therefore, NO_x is determined to meet the RFP requirements.

FIGURE 6-1
NO_x RFP TOWARD ATTAINMENT:
ORANGE DASHED LINE PRESENTS THE LINEAR INTERPOLATION FROM BASE YEAR TO
ATTAINMENT SCENARIO EMISSIONS AND BLUE SOLID LINE PRESENTS ANTICIPATED
PROGRESS TOWARD ATTAINMENT

PM2.5

Direct PM2.5 emissions are expected to decrease in a generally linear fashion from the base year to the attainment scenario, as shown in Figure 6-2. The direct PM2.5 emission reductions anticipated from the baseline reductions and line item adjustments are sufficient to meet or exceed the RFP targets. Therefore, direct PM2.5 is determined to meet the RFP requirements.

FIGURE 6-2

ATTAINMENT SCENARIO EMISSIONS AND BLUE SOLID LINE PRESENTS ANTICIPATED
PROGRESS TOWARD ATTAINMENT

Ammonia

RFP for ammonia utilizes a stepwise approach as justified earlier in this chapter. Figure 6-3 illustrates a parabolic ammonia trend. As explained in the stepwise justification, the projected growth in ammonia emissions between 2018 and 2025 is mainly driven by increases in the human and pet population that outpace emission reductions. However, the pace of ammonia emission reductions accelerates after 2025 due to increasing penetration of zero emission technologies especially in the on-road sector. CARB regulations such as Advanced Clean Cars II and Advanced Clean Fleets contribute to these emission reductions. The control strategy also includes South Coast AQMD's ammonia measures, BCM-08 through BCM-11, and CARB's Zero Emissions Truck Measure which are expected to further reduce ammonia emissions. In 2028 and 2030, these regulations result in ammonia reductions that outpace increases due to population growth. While 2030 is projected to have higher emissions than 2018, this marginal increase will not hinder attainment of the 2012 annual PM_{2.5} NAAQS in 2030. In addition, the implementation of zero emission vehicles and technologies will continue beyond 2030 and lower ammonia emissions even further. Therefore, ammonia is determined to meet the RFP requirements.

Quantitative Milestones for South Coast AQMD Stationary Source Regulations

The RFP and quantitative milestone demonstrations in this Plan rely, in part, on NO_x reductions from South Coast AQMD rules, the most significant of which is Rule 1109.1. South Coast AQMD will also report on the adoption and implementation of stationary source measures as specified in Chapter 4.

The applicable quantitative milestone years for the 2012 12 µg/m³ annual PM_{2.5} standard are 2025, 2028, and 2031.

For the 2025 milestone year, South Coast AQMD will report on the following:

- Implementation from 2022 through 2025 of Rule 1109.1, which establishes NO_x and CO emission limits for combustion equipment at petroleum refineries and facilities with operations related to petroleum refineries.
- Adoption and implementation of applicable PM_{2.5} Plan measures according to the schedule specified in Chapter 4.

For the 2028 milestone year, South Coast AQMD will report on the following:

- Implementation from 2026 through 2028 of Rule 1109.1, which establishes NO_x and CO emission limits for combustion equipment at petroleum refineries and facilities with operations related to petroleum refineries.
- Adoption and implementation of applicable PM_{2.5} Plan measures according to the schedule specified in Chapter 4.

For the 2031 milestone year, South Coast AQMD will report on the following:

- Implementation from 2029 through 2031 of Rule 1109.1, which establishes NO_x and CO emission limits for combustion equipment at petroleum refineries and facilities with operations related to petroleum refineries.
- Adoption of applicable PM_{2.5} Plan measures since the 2028 milestone year.
- Demonstration of implementation of all PM_{2.5} Plan measures with committed adoption and implementation schedules.
- Demonstration that the aggregate emission reduction commitment was achieved for the 2030 attainment year.

Quantitative Milestones for State Mobile Source Regulations

CARB will work closely with South Coast AQMD to report on the milestones identified in this Plan for the applicable milestone years. CARB will report on milestones for implementation of mobile source measures that contribute significant emissions reductions included in the reasonable further progress demonstration through the 2031 milestone year. These regulations were originally set forth as measure commitments in the 2016 State Strategy for the State Implementation Plan (2016 State SIP Strategy) and the 2022 State Strategy for the State Implementation Plan (2022 State SIP Strategy).

For the 2025 milestone year, CARB is reporting on the following three milestones:

- Implementation from 2022 through 2025 of the Clean Truck Check Program, previously known as the Heavy-Duty Vehicle Inspection and Maintenance Program, which ensures that vehicles' emissions control systems are properly functioning when traveling on California's roadways;
- Implementation from 2022 through 2025 of the Advanced Clean Fleets Regulation which focuses on strategies to ensure that the cleanest vehicles are deployed by government, business, and other entities in California to meet their transportation needs; and
- Implementation from 2022 through 2025 of the In-Use Off-Road Diesel-Fueled Fleets Regulation which requires fleets operating in-use off-road diesel equipment to meet an annual fleet average emissions target that decreases over time.

For the 2028 milestone year, CARB is reporting on the following three milestones:

- Implementation from 2026 through 2028 of the Heavy-Duty Vehicle Inspection and Maintenance Program, also known as Clean Truck Check, which ensures that vehicles' emissions control systems are properly functioning when traveling on California's roadways;
- Implementation from 2026 through 2028 of the Advanced Clean Fleets Regulation which focuses on strategies to ensure that the cleanest vehicles are deployed by government, business, and other entities in California to meet their transportation needs; and
- Implementation from 2026 through 2028 of the In-Use Off-Road Diesel-Fueled Fleets Regulation which requires fleets operating in-use off-road diesel equipment to meet an annual fleet average emissions target that decreases over time.

For the 2031 milestone year, CARB is reporting on the following milestone:

- The status of new CARB SIP measures adopted between 2024 and 2030 per the schedule included in the adopted South Coast 12 $\mu\text{g}/\text{m}^3$ annual PM_{2.5} Plan that provide for attainment of the 12 $\mu\text{g}/\text{m}^3$ PM_{2.5} annual standard in 2030.

Transportation Conformity

CAA Section 176(c) establishes transportation conformity requirements which are intended to ensure that transportation activities do not interfere with air quality progress. The CAA requires that transportation plans, programs, and projects that obtain federal funds or approvals conform to applicable SIPs before being approved by a Metropolitan Planning Organization (MPO). –Conformity to a SIP means that proposed activities must not:

- (1) Cause or contribute to any new violation of any standard;
- (2) Increase the frequency or severity of any existing violation of any standard in any area; or
- (3) Delay timely attainment of any standard or any required interim emission reductions or other milestones in any area.

A SIP that analyzes the region's total emissions inventory from all sources is necessary for purposes of demonstrating RFP and attainment. The portion of the total emissions inventory from on-road highway and transit vehicles in these analyses becomes the Motor Vehicle Emissions Budget (MVEB).¹⁶ Budgets are set for each criteria pollutant or its applicable precursor(s), for all RFP milestone years and the attainment year. Subsequent transportation plans and programs produced by transportation planning agencies are required to conform to the SIP by demonstrating that the emissions from the proposed plan, program, or project do not exceed the MVEB.

PM2.5 Requirements for Conformity

The U.S. EPA has promulgated separate rules addressing the PM2.5 emission categories and precursors that must be considered in PM2.5 transportation conformity determinations.

PM2.5 Motor Vehicle Emission Category Requirements

Guidance on the motor vehicle emission categories that must be considered in transportation conformity determinations can be found in the July 1, 2004, Final Rule amending the Transportation Conformity Rule to implement criteria and procedures for the 8-hour ozone and PM2.5 standards:¹⁷

[A]ll regional emissions analyses in PM2.5 nonattainment and maintenance areas [must] consider directly emitted PM2.5 motor vehicle emissions from the tailpipe, brake wear, and tire wear...Sections IX. and X. [of the Final Rule] provide information on when re-entrained

¹⁶ Federal transportation conformity regulations are found in 40 CFR Part 51, subpart T – Conformity to State or Federal Implementation Plans of Transportation Plans, Programs, and Projects Developed, Funded or Approved Under Title 23 U.S.C. of the Federal Transit Laws. Part 93, subpart A of this chapter was revised by the EPA in the August 15, 1997 Federal Register.

¹⁷ Transportation Conformity Rule Amendments for the New 8-hour Ozone and PM2.5 National Ambient Air Quality Standards and Miscellaneous Revisions for Existing Areas; Transportation Conformity Rule Amendments: Response to Court Decision and Additional Rule Changes, 69 Fed. Reg. 40004 (July 1, 2004)

road dust and construction-related dust must also be included in PM_{2.5} conformity analyses...[T]he analysis for direct PM_{2.5} must include:

- tailpipe exhaust particles,
- brake and tire wear particles,
- re-entrained road dust, if before a SIP is submitted to U.S. EPA or the state air agency has made a finding of significance or if the applicable or submitted SIP includes re-entrained road dust in the approved or adequate budget, and
- fugitive dust from transportation-related construction activities, if the SIP has identified construction emissions as a significant contributor to the PM_{2.5} problem.¹⁸

PM_{2.5} Motor Vehicle Emission Precursor Requirements

Following the July 1, 2004, Final Rule identifying the motor vehicle emission categories that must be considered in transportation conformity determinations, U.S. EPA issued the May 6, 2005, Final Rule¹⁹ amending the Transportation Conformity Regulation. In this Final Rule, U.S. EPA identifies four transportation-related precursors that result in PM_{2.5} formation—~~nitrogen oxides (NO_x), volatile organic compounds (VOCs), sulfur oxides (SO_x),²⁰ and ammonia (NH₃)~~—for consideration in the conformity process in PM_{2.5} nonattainment and maintenance areas.²¹ Of these PM_{2.5} precursors, NO_x must be included in the regional transportation conformity determination unless it is found to be an insignificant contributor to the formation of PM_{2.5} in the region, per Section 93.102(b)(2)(iv) of the Conformity Regulation. Conversely, VOCs, SO_x, and NH₃ are not required unless these precursors are found to be significant contributors to the formation of PM_{2.5} in the region or are included in the RFP demonstration.²² In this plan, NH₃ emissions are considered in the MVEB as NH₃ emissions are included in the RFP demonstration.

¹⁸ 69 FR 40331-40333. Codified in Sections 93.102(b)(1) and (3) and Section 93.122(f) of the Conformity Regulation.

¹⁹ Transportation Conformity Rule Amendments for the New PM_{2.5} National Ambient Air Quality Standard: PM_{2.5} Precursors, 70 Fed. Reg. 24280 (June 1, 2005)

²⁰ U.S. EPA revised the transportation conformity rule to revise PM_{2.5} precursors from SO_x to SO₂ for consistency with the broader PM_{2.5} implementation strategy. (Transportation Conformity Rule Amendments To Implement Provisions Contained in the 2005 Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users (SAFETEA-LU), 73 Fed. Reg. 4435 (Jan. 24, 2008))

Conformity Budgets

Introduction

The California Air Resources Board (CARB) has prepared the ~~motor vehicle emissions budget (MVEB)~~²³ for the South Coast Attainment Plan for the 2012 Annual PM2.5 National Ambient Air Quality Standard (NAAQS).²⁴ The MVEB is the maximum allowable emissions from motor vehicles within a nonattainment area and is used to determine whether transportation plans and projects conform to the applicable state implementation plan (SIP).

Transportation conformity is the federal regulatory procedure for linking and coordinating the transportation and air quality planning processes through the MVEB established in the SIP. Under section 176(c) of the Clean Air Act (Act), federal agencies may not approve or fund transportation plans and projects unless they are consistent with the regional SIP. In addition, conformity with the SIP requires that transportation activities do not (1) cause or contribute to new air quality violations, (2) increase the frequency or severity of any existing violation, or (3) delay the timely attainment of NAAQS. Therefore, quantifying on-road motor vehicle emissions and comparing those emissions with a budget established in the SIP determine transportation conformity between air quality and transportation planning.

The MVEBs are set for each criteria pollutant or its precursors for each milestone year and the attainment year of the SIP. Subsequent transportation plans and programs produced by transportation planning agencies must demonstrate that the emissions from the proposed plan, program, or project do not exceed the MVEBs established in the applicable SIP. The MVEBs established in this SIP apply as a "ceiling" or limit on transportation emissions for the Southern California Association of Governments (SCAG) for the years in which they are defined and for all subsequent years until another year for which a different budget is specified, or until a SIP revision modifies the budget. For the South Coast Air Quality Management District's (District) annual PM2.5 attainment plan, the milestone years, attainment year of the SIP, and post-attainment milestone years (also referred to as the plan analysis years) are 2025, 2028, 2030, and 2031.

Methodology

The MVEB for the South Coast annual PM2.5 attainment plan is established based on guidance from the U.S. EPA on the motor vehicle emission categories and precursors that must be considered in transportation conformity determinations as found in the transportation conformity regulation and final rules as described below. The MVEB must be clearly identified, precisely quantified, and consistent with

²³ Federal transportation conformity regulations are found in 40 CFR Part 51, subpart T – Conformity to State or Federal Implementation Plans of Transportation Plans, Programs, and Projects Developed, Funded or Approved Under Title 23 U.S.C. of the Federal Transit Laws. Part 93, subpart A of this chapter was revised by the EPA in the August 15, 1997 Federal Register.

²⁴ National Ambient Air Quality Standards for PM, <https://www.epa.gov/pm-pollution/national-ambient-air-quality-standards-naaqs-pm#rule-summary>

applicable Act requirements. Further, it should be consistent with the South Coast PM2.5 Attainment Plan's emission inventory and control measures.

The South Coast annual PM2.5 attainment plan establishes the MVEB only for primary emissions of PM2.5 from motor vehicle exhaust, tire and brake wear, and paved and unpaved road dust, as well as for the precursors of NOx and NH3. This section discusses budgets that have been set for annual average daily emissions in the analysis years 2025, 2028, 2030, and 2031. The MVEB presented below uses emission rates from California's motor vehicle emission model, EMFAC2021 (V.1.0.2),²⁵ with South Coast activity data (Vehicle Miles Traveled, i.e., VMT, and speed distributions), along with California Emissions Projection Analysis Model (CEPAM) 2022v1.01. The activity data are from the region's 2020 Regional Transportation Plan (RTP).²⁶ Thus, they are consistent with the attainment demonstration for the SIP.

On November 15, 2022, the U.S. EPA approved EMFAC2021 for use in SIPs and demonstrating transportation conformity.²⁷ The EMFAC model estimates emissions from two combustion processes (running and start exhaust) and four evaporative processes (hot soak, running losses, diurnal, and resting losses). Further, the estimated emissions were adjusted for the Heavy-Duty Inspection and Maintenance (HD I/M) Program,²⁸ the Advanced Clean Fleets (ACF) program,²⁹ the Advanced Clean Cars II (ACCII) program,³⁰ and the Clean Trucks Plan.³¹

The MVEB for the South Coast annual PM2.5 attainment plan was developed to be consistent with the on-road emissions inventory³² and attainment demonstration using the following method:

- (1) Used the EMFAC2021 model to produce the on-road motor vehicle emissions totals (average annual day) for the appropriate pollutants (NOx, NH3, and PM2.5)³³ using the 2020 RTP activity data.
- (2) Applied the off-model adjustments (HD I/M, ACF, ACCII, and Clean Trucks Plan) to account for recently adopted regulations.
- (3) Used CEPAM2022 model to estimate on-road construction dust, paved road dust, and unpaved road dust for PM2.5.
- (4) Rounded the totals for NOx, NH3, and PM2.5 to the nearest ton.

Motor Vehicle Emissions Budget

The MVEB in Table ~~6-9~~ was established according to the methodology outlined above and in consultation with SCAG, the District, U.S. EPA, Federal Highway Administration (FHWA), and Federal Transit Administration (FTA). The MVEB is consistent with the emission inventories and control measures in the PM2.5 attainment plan. This budget will be effective once U.S. EPA determines it is adequate or approved.

Table 6-9 contains the Summary MVEB for the South Coast Air Basin. It includes pollutants of NO_x, NH₃, and PM2.5 emissions for milestone and attainment years using the EMFAC2021 model and 2020 RTP activity data.

TABLE 6-9

Fulfillment of New Source Review Requirements

CAA Section 172(c) requires permits for the construction and operation of new or modified major stationary sources. New Source Review (NSR) for major and in some cases minor sources of PM_{2.5} and its precursors is presently addressed through South Coast AQMD's NSR and RECLAIM programs (Regulations XIII and XX, respectively). Both programs are applicable to sources located in the South Coast AQMD jurisdiction, including the South Coast Air Basin and the Coachella Valley. Regulation XIII establishes the federal and State mandated pre-construction review program for new, modified, or relocated sources. The NSR program is a critical component of South Coast AQMD's attainment strategy and ensures that all new and modified sources install BACT and their emission increases are fully offset with creditable emission reductions.

The components of South Coast AQMD's NSR program are contained within Regulation XIII. Rule 1325 was adopted June 3, 2011 to incorporate the U.S. EPA's requirements for PM_{2.5} and its precursors into Regulation XIII. The rule mirrors federal requirements which include the definition of major source, significant emissions rate, offset ratios, and the applicability requirements of Lowest Achievable Emission Rate (LAER), facility compliance, offsets, and control of PM_{2.5} precursors. In 2021, U.S. EPA approved Rule 1325 as meeting all applicable NSR requirements.³⁴

RECLAIM facilities are currently not subject to emission offsets for NO_x and SO_x under Regulation XIII, however, these facilities are instead subject to NO_x and SO_x emission offsets under Regulation XX. Under existing NSR in Regulation XIII and RECLAIM programs in Regulation XX, major stationary sources of NO_x and SO_x are already subject to emission offsets. The 2016 AQMP included a control measure, CMB-05 - Further NO_x Reductions from RECLAIM Assessment, to achieve an additional five tons per day of NO_x emissions as soon as practicable, but no later than 2025, and to transition RECLAIM to a command-and-control regulatory structure. The transition will include requiring former RECLAIM sources to be subject to Regulation XIII for NO_x and SO_x as applicable. Regulation XIII will be updated to reconcile the program with U.S. EPA's 2002 NSR Reform.³⁵

VOC and ammonia emissions are also subject to BACT under existing NSR. VOC emissions are required to be offset when a new or modified source has the potential to emit 4 tons per year or more of VOC. Ammonia emission sources have not historically been subject to NSR offset requirements. However, for permitted ammonia sources, Rule 1303 (NSR Requirements) requires denial of "the Permit to Construct for any relocation, or for any new or modified source which results in an emission increase of any nonattainment air contaminant, any ozone depleting compound, or ammonia, unless BACT is employed for the new or relocated source or for the actual modification to an existing source." BACT shall be at least as stringent as LAER as defined in CAA Section 171(3); therefore, South Coast AQMD's current regulations requiring BACT

³⁴ Air Plan Approval; California; South Coast Air Quality Management District; Stationary Source Permits, 86 Fed. Reg. 58592 (Oct. 22, 2021)

³⁵ Prevention of Significant Deterioration (PSD) and Nonattainment New Source Review (NSR): Baseline Emissions Determination, Actual-to-Future-Actual Methodology, Plantwide Applicability Limitations, Clean Units, Pollution Control Projects, 67 Fed. Reg. 80186 (Dec. 31, 2002)

comply with the federal LAER requirements.

Major Source Threshold

The NSR permitting program relies on emissions thresholds to determine when certain requirements apply to new stationary sources and to modifications of existing stationary sources. If a new or modified facility will emit PM_{2.5} or PM_{2.5} precursor emissions greater than the major source threshold, the facility is considered a major source. Under a “serious” nonattainment classification, the major source threshold is defined as a potential to emit 70 or more tons per year of PM_{2.5} or PM_{2.5} precursors. To comply with federal requirements for “serious” nonattainment areas, Rule 1325 was amended on November 4, 2016 to update the Major Polluting Facility definition to align the associated major source emission threshold at 70 tons per year for PM_{2.5} and PM_{2.5} precursors. VOC and ammonia were added to the Rule 1325 definition of “precursors” and a VOC and ammonia threshold at 40 tons per year was added as part the definition of “significant” which is used in the determination of a “major modification.” The SO_x major polluting facility threshold defined in Rule 1302 was also lowered from 100 to 70 tons per year. While the 2016 amendment expanded the definition of “precursors,” it did not expand the definition of “regulated NSR pollutant” to explicitly reference VOC and NH₃ as PM_{2.5} precursor. For this reason, U.S. EPA conditionally approved Rule 1325 based on a commitment to amend Rule 1325 to expand the definition of “regulated NSR pollutant.”³⁶ South Coast AQMD subsequently amended Rule 1325 on January 4, 2019 to correct this deficiency and U.S. EPA approved the amendment into the SIP.³⁷

PM Precursor Requirement in Nonattainment NSR

CAA Section 189(e) states that control requirements applicable to plans in effect for major stationary PM sources shall also apply to major stationary sources of PM precursors, except where such sources do not contribute significantly to PM levels which exceed the standard in the area. A state is required to conduct a Nonattainment NSR (NNSR) precursor demonstration, which evaluates the sensitivity of PM_{2.5} levels to an increase in emissions of a precursor, to exempt the precursor from NSR requirements.³⁸ This differs from a comprehensive precursor demonstration, which evaluates the sensitivity of PM_{2.5} levels to a decrease in emissions of a precursor. South Coast AQMD has not conducted an NNSR precursor demonstration and is not seeking to exempt precursors from NSR requirements. Therefore, Rule 1325 satisfies CAA Section 189(e) by addressing all precursors of PM_{2.5} including NO_x, VOC, ammonia, and SO_x.

³⁸ Fine Particulate Matter National Ambient Air Quality Standards: State Implementation Plan Requirements, 81 Fed. Reg. 58010 (Aug. 24, 2016)

Contingency Measures

Clean Air Act Section 172(c)(9) requires a SIP to provide for the implementation of specific measures to be undertaken if the nonattainment area fails to make RFP, or to attain the NAAQS by the applicable attainment date. Such contingency measures need to take effect within 60 days in any such case without further action by South Coast AQMD. Furthermore, contingency measures must achieve ~~their full~~ emission reductions within 2 years of being triggered. The U.S. EPA provides further details in its Draft Contingency Measures Guidance.³⁹

Rule 445 (Wood-Burning Devices)

To comply with PM_{2.5} contingency requirements, South Coast AQMD amended Rule 445 (Wood-Burning Devices) on June 5, 2020 to include multiple triggers for contingency measures. Rule 445 was subsequently approved by U.S. EPA, excluding paragraph (g) (Ozone Contingency Measures) and paragraph (k) (Penalties), as fulfilling PM_{2.5} contingency measure requirements.⁴⁰ Rule 445 contains four PM_{2.5} contingency measures, each of which impose lower curtailment thresholds upon any of U.S. EPA's findings of failure to comply or attain as specified in 40 CFR §51.1014(a). The first Rule 445 contingency measure was triggered upon U.S. EPA's finding of failure to attain the 2006 24-hour PM_{2.5} standard.⁴¹ As a result, Rule 445 wood burning curtailment applies to the entire Basin when PM_{2.5} is forecast to be higher than 29 µg/m³ on any day during the wood-burning season.

~~Each subsequent finding by the U.S. EPA will trigger increasingly stringent requirements by lowering the curtailment threshold in the rule. The PM_{2.5} reductions for imposing the remaining thresholds of 28, 27, and 26 µg/m³ are expected to be 20.9, 13.9 and 19.1 tpy, respectively. If future amendments to Rule 445 modify the curtailment threshold, South Coast AQMD commits to consider retaining the existing structure for contingency measures.~~ Control measure BCM-18 proposes to lower the Basin-wide curtailment threshold in Rule 445 from 29 µg/m³ to 25 µg/m³. To satisfy contingency measure requirements, South Coast AQMD proposes to further lower the curtailment threshold to 23 µg/m³ upon any of the applicable triggering events described earlier.

One Year's Worth of Emission Reductions

The reductions from contingency measures are required to satisfy U.S. EPA's definition of one year's worth (OYW) of reductions, which is given by the following equation:

³⁹ U.S. EPA DRAFT: Guidance on the Preparation of State Implementation Plan Provisions that Address the Nonattainment Area Contingency Measure Requirements for Ozone and Particulate Matter, <https://www.epa.gov/system/files/documents/2023-03/CMTF%202022%20guidance%203-17-23.pdf>

⁴⁰ Air Plan Approval; California; Los Angeles — South Coast Air Basin, 87 Fed. Reg. 12866 (March 8, 2022)

⁴¹ Finding of Failure To Attain the 2006 24-Hour Fine Particulate Matter Standards; California; Los Angeles- South Coast Air Basin, 85 Fed. Reg. 57733 (Sept. 16, 2020)

$$\frac{(base\ year\ EI - attainment\ year\ EI)}{(attainment\ year - base\ year)} \div base\ year\ EI \times attainment\ year\ EI$$

Thus, OYW of reductions represents the average emission reductions expected per year over the planning timeline, expressed as a percentage of the base year emission inventory (EI), applied to the attainment year EI. Table 6-10 provides the calculated OYW of reductions for PM2.5 and NOx. Ammonia is omitted from Table 6-10 as its emissions increase between 2018 and 2030 and it would be unreasonable to propose a contingency measure that results in an emissions increase.

TABLE 6-10
OYW OF PM2.5 AND APPLICABLE PRECURSOR REDUCTIONS BASED ON 2018 BASE YEAR AND 2030 ATTAINMENT YEAR EI (TPD)

	NOx	PM2.5
2018 Base Year EI	383.02	56.04
2030 Attainment Year EI	175.37	52.68
OYW of Reductions	7.92	0.26

The PM2.5 Plan includes two contingency measures – further lowering the curtailment threshold in Rule 445 and CARB’s Smog Check Contingency Measure. The Rule 445 contingency measure only quantified reductions for PM2.5 emissions as concurrent reductions of NOx are expected to be small. A comparison of the emission reductions achieved by these contingency measures to OYW of reductions is provided in Table 6-11.

TABLE 6-11
EMISSION REDUCTIONS PROVIDED BY CONTINGENCY MEASURES AND COMPARISON TO OYW (TPD)

	NOx	PM2.5
Rule 445	<u>0.0</u>	<u>0.32</u>
CARB’s Smog Check Contingency Measure	<u>0.30</u>	<u>0.0</u>
Percentage of OYW of Reductions	<u>3.8</u>	<u>123</u>

While Rule 445 achieves OYW of PM2.5 reductions, CARB’s Smog Check Contingency Measure achieves less than OYW of NOx reductions. If contingency measures are unable to provide OYW of reductions, U.S. EPA requires that agencies provide a reasoned justification for achieving a lesser amount of reductions. While the Draft Contingency Measures Guidance outlines a process for developing such a justification, however, the guidance has not yet been finalized and is therefore subject to revision. Nevertheless, based on the Draft Contingency Measures Guidance and currently available information, staff developed a justification for achieving less than OYW of NOx reductions and included it in Appendix V. The justification includes evaluation of potential contingency measures for all sources of PM2.5, ammonia, and NOx emissions in the Basin. South Coast AQMD includes feasible ammonia measures in the control strategy; as such, these measures are ineligible for consideration as contingency measures. Similarly, no further contingency measures that achieve

NOx reductions were identified. Finally, since Rule 445 provides OYW of PM2.5 reductions, additional contingency measures for PM2.5 are not needed.

Reductions from the remaining contingency triggers in Rule 445 are compared to OYW's of reductions in Table 6-11. The difference between the cumulative reductions of all contingency triggers and OYW of reductions is also displayed for comparison.

TABLE 6-11
RULE 445 CONTINGENCY MEASURE REDUCTIONS (TPY)

Pollutant	Rule 445 Curtailment Threshold			Difference [OYW Reductions— Cumulative Reductions]
	28 µg/m³	27 µg/m³	26 µg/m³	
PM2.5	20.9	13.9	19.1	42.2
NOx	0	0	0	2,890.8

While Rule 445 satisfies the triggering mechanism requirement and results in PM2.5 reductions, it does not achieve OYW of reductions as required by U.S. EPA. Concurrent reductions of other pollutants are expected to be small and were not quantified. If contingency measures are unable to provide OYW of reductions, U.S. EPA requires that agencies provide a reasoned justification for achieving a lesser amount of reductions. While the Draft Contingency Measures Guidance outlines a process for developing such a justification, the guidance has not yet been finalized and is therefore subject to revision. Nevertheless, based on the Draft Contingency Measures Guidance and currently available information, staff developed a justification for achieving less than OYW of reductions and included it in Appendix V.

South Coast AQMD's Opportunities for Contingency Measures

The South Coast Air Basin faces some of the most difficult air quality challenges in the nation and, accordingly, South Coast AQMD has one of the most stringent stationary source control programs in the country. South Coast AQMD recently expanded its regulatory activities to mobile sources using innovative approaches such as indirect source rules, voluntary Memoranda of Understanding, and incentive measures. Due to the stringency of those existing requirements, further opportunities for a triggered contingency measure that can be implemented by South Coast AQMD and result in OYW of emission reductions within two years of triggering are non-existent. Even if there were measures capable of achieving this level of emission reductions, they would not be withheld for contingency purposes. Instead, they would be adopted to improve air quality in furtherance of the obligation to meet the NAAQS as soon as feasible. As demonstrated in Appendix V, staff did not identify any other feasible measures that satisfy contingency measure criteria.

Conclusion

The PM2.5 Plan complies with all federal CAA requirements. The most significant CAA requirements, including

the emissions inventory, control strategy, and attainment demonstration, are discussed in Chapters 3 through 5. This chapter demonstrates compliance with other CAA requirements. Further details showing compliance with control strategy and contingency measure requirements are provided in Appendices III, IV and V.

CHAPTER 7

Environmental Justice

- The impacts of air pollution are not distributed equitably throughout the South Coast Air Basin, with some communities bearing much higher air pollution burdens.
- The Draft PM2.5 Plan includes control measures to reduce the levels of PM2.5, a regional pollutant in the entire Basin to meet the annual PM2.5 NAAQS. South Coast AQMD, however, addresses disproportionate impacts of local air pollution in disadvantaged communities through the AB 617 program.
- Environmental Justice (EJ) communities typically experience higher PM2.5 levels and higher cancer risks from toxic air pollutants than other regions in the Basin.
- Measures associated with the Draft PM2.5 Plan will help reduce air pollution in disproportionately impacted areas.
- In the implementation of both existing and future incentive programs, South Coast AQMD will continue to prioritize EJ areas to address the issues of the most disadvantaged communities.

Introduction

Environmental Justice (EJ) communities are disproportionately impacted by various types of pollution and experience health, social, and economic inequities. These inequities can also make residents of EJ communities more vulnerable to the effects of environmental pollution. These communities are often located near multiple air pollution sources including both mobile sources and commercial and industrial facilities. For example, communities adjacent to ports, rail yards and warehouses are exposed to higher levels of emissions from the associated ships, trains, and trucks, including diesel particulate matter, a carcinogen. Communities near refineries and other industries can also suffer from higher levels of air pollution.

The California Office of Environmental Health Hazard Assessment (OEHHA) developed the California Communities Environmental Health Screening Tool (CalEnviroScreen) to identify disadvantaged communities across California based on pollution exposure and population characteristics. This information can be used to advise and assist South Coast AQMD in protecting and improving public health in the most impacted communities through the reduction and prevention of air pollution. While there is no universal definition for what constitutes an EJ community, one that is commonly used is the Senate Bill (SB) 535 definition of disadvantaged communities (DACs)¹. These are defined as:

1. Census tracts receiving the highest 25 percent of overall scores in CalEnviroScreen 4.0 (1,984 tracts).
2. Census tracts lacking overall scores in CalEnviroScreen 4.0 due to data gaps, but ~~receiving that~~ receive the highest 5 percent of CalEnviroScreen 4.0 cumulative pollution burden scores (19 tracts).
3. Census tracts identified in the 2017 DAC designation as disadvantaged, regardless of their scores in CalEnviroScreen 4.0 (307 tracts).
4. Lands under the control of federally recognized Tribes.

All calculations and maps in this section that refer to EJ communities are consistent with this definition. The map of EJ communities alongside major roads within the Basin are presented in Figure 7-1.

SB 535 Disadvantaged Communities

South Coast Air Basin

FIGURE 7-1

MAP OF ENVIRONMENTAL JUSTICE COMMUNITIES (VIOLET) WITHIN THE SOUTH COAST AIR BASIN. PRIMARY AND SECONDARY ROADS ARE IN RED

The PM_{2.5} Plan focuses on steps needed to attain the 2012 annual PM_{2.5} standard. As further described in this chapter, environmental justice communities typically experience worse levels of PM_{2.5} than other areas in the Basin. The control strategy proposed in this Plan, which includes transitioning to zero emission technologies where feasible and the cleanest available technologies where zero emission technologies are not feasible, will substantially reduce PM_{2.5} emissions. This includes diesel particulate matter, a powerful cancer-causing pollutant, and other mobile source pollutants that go on to form PM_{2.5}, such as nitrogen oxides. As shown in Figure 7-2 below, the highest levels of air toxics risk are around our ports, rail yards, and major transportation corridors, where many of our EJ communities are located. About 88 percent of those risks are from pollutants associated with mobile sources, with diesel particulate matter alone accounting for about half of those risks. Cleaning up emissions from truck, ship, locomotive, and aircraft fleets will therefore substantially reduce health risks from air pollution in impacted communities, while also putting the region on a path to meet federal air quality standards.

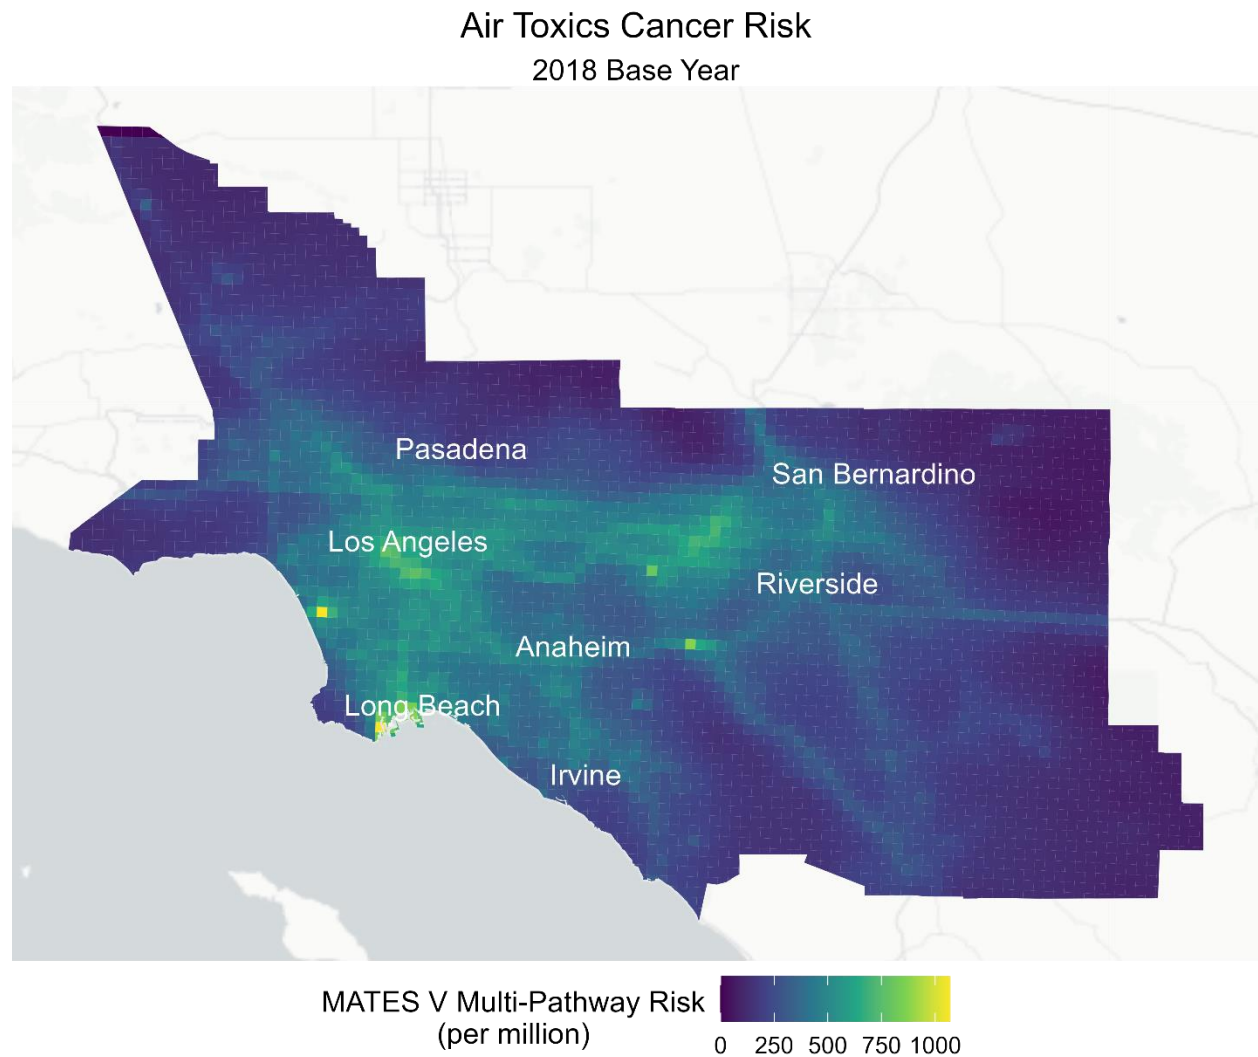

FIGURE 7-2
MODELED MULTI-PATHWAY AIR TOXICS CANCER RISK FROM MATES V IN THE SOUTH
COAST AIR BASIN²

² South Coast AQMD. Multiple Air Toxics Exposure Study in South Coast AQMD. South Coast Air Quality Management District, Aug. 2021, <https://www.aqmd.gov/docs/default-source/planning/mates-v/mates-v-final-report-9-24-21.pdf?sfvrsn=6>.

The purpose of this chapter is to describe air quality impacts experienced in EJ communities and projected future air quality and attainment of the 2012 annual PM_{2.5} standard. While the work described in this chapter will help reduce localized impacts, South Coast AQMD understands that work is ongoing, and much more will need to be done to address historic environmental injustice. South Coast AQMD is committed to continuing work with impacted communities, listening to their concerns, and to the greatest extent possible, addressing their concerns. Environmental justice principles center the importance of public participation in decision-making. To that end, as highlighted in chapter 8, public participation and outreach are critical to the development of the PM_{2.5} Plan. Relevant stakeholders in the development of the PM_{2.5} Plan include environmental justice organizations, environmental advocacy groups, and members of the public. Outreach occurs in-person and remote participation at Advisory Group Meetings, South Coast AQMD Governing Board Meetings, and Regional Public Hearings. For these programs, South Coast AQMD releases Spanish-language versions of meeting notices, agendas, and presentations alongside live Spanish translation.

Environmental Justice Communities

Environmental Justice, or "EJ" has been defined by South Coast AQMD as "equitable environmental policymaking and enforcement to protect the health of all residents, regardless of age, culture, ethnicity, gender, race, socioeconomic status, or geographic location, from the health effects of air pollution." While there are many approaches for identifying EJ communities, throughout this ~~Draft-PM_{2.5}~~ Plan, we consider EJ communities as the disadvantaged communities defined under SB 535.³ By that definition, approximately 42 percent of South Coast Air Basin residents are in EJ communities. Race and ethnicity are not included in the CalEnviroScreen population indicators, but as discussed in the OEHHA Analysis of Race/Ethnicity and CalEnviroScreen results,⁴ people of color disproportionately reside in highly impacted communities in California. These disparities are also clear in the South Coast Air Basin, reflecting the impact of institutional and structural racism that has created unequal pollution burdens and health impacts for different groups (Figure 7-3). Mental and physical disabilities are not considered in this analysis since they are not accounted for in the CalEnviroScreen.

³ Refer the 2nd paragraph of this chapter for the definition of EJ community

⁴OEHHA. Analysis of Race/Ethnicity and CalEnviroScreen 4.0 Scores. California Office of Environmental Health Hazards Assessment, Oct. 2021.

FIGURE 7-3
RACIAL AND ETHNIC MAKEUP OF EJ AND NON-EJ COMMUNITIES IN SOUTH COAST AIR BASIN (2021)

Assembly Bill 617

The PM2.5 Plan is designed to address regional air pollution, however, South Coast AQMD recognizes there is still much work to be done to reduce local exposures within EJ communities. Statewide and South Coast AQMD environmental justice efforts, such as the Assembly Bill 617 (AB 617)⁵ program, seek to collaboratively address environmental challenges in communities that are disproportionately impacted by pollution and more vulnerable to the health effects of pollution.

⁵ California Health and Safety Code § 44391.2

AB 617 Communities South Coast Air Basin

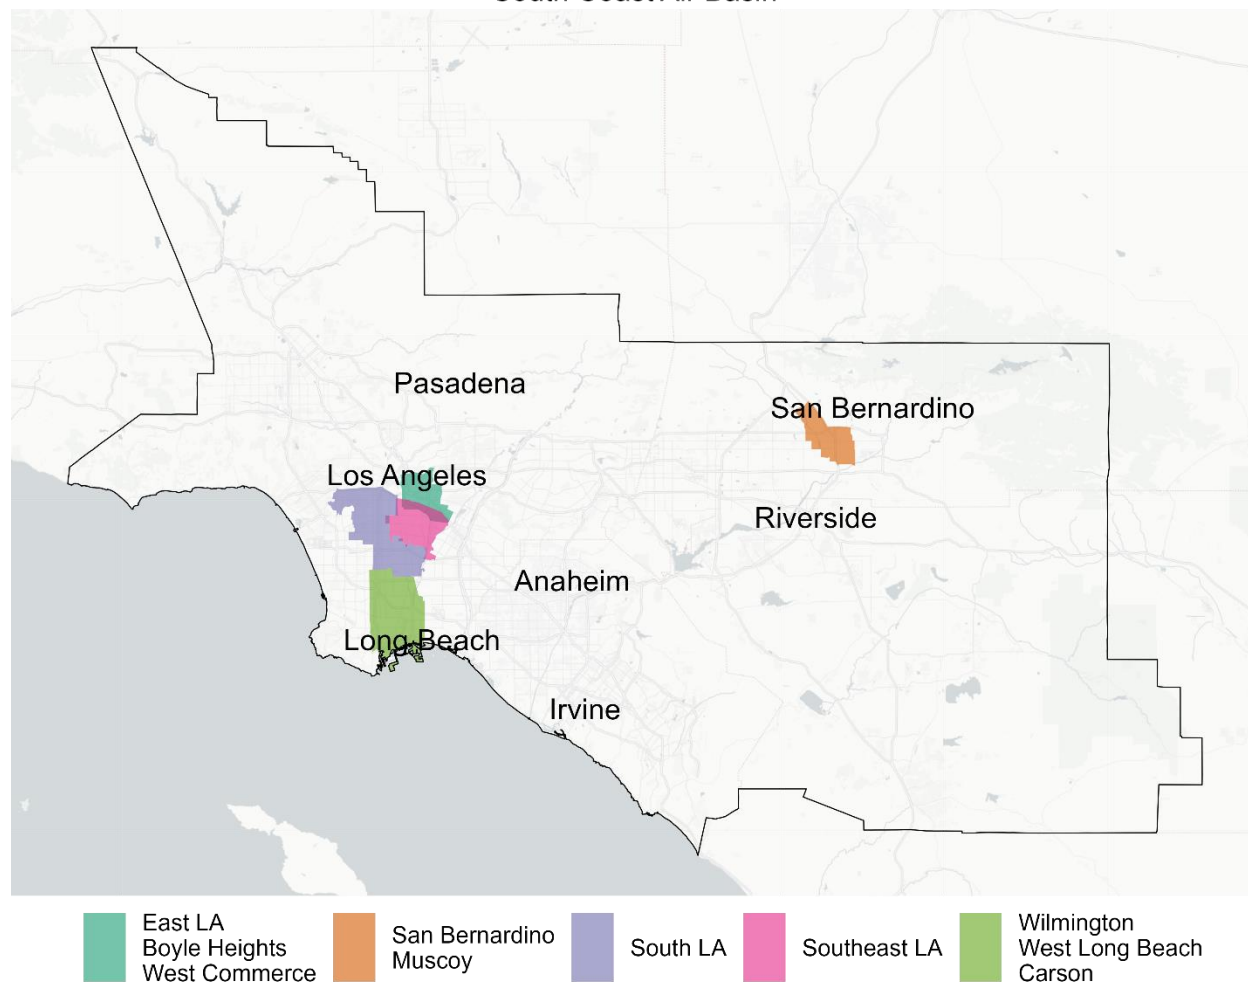

FIGURE 7-4
MAP OF AB 617 COMMUNITIES WITHIN THE SOUTH COAST AIR BASIN

AB 617 was signed into California law on July 26, 2017, and focused on addressing disproportionate impacts of local air pollution in EJ communities. The AB 617 program requires local air districts and California Air Resources Board (CARB) to reduce air pollution in disproportionately burdened communities, improve accountability and transparency, and promote collaborative partnerships with community stakeholders. AB 617 communities are designated by CARB, and they specify the plan(s) for the community as either an emission reduction program, air monitoring program, or both.

To meet the emission reduction program requirements, South Coast AQMD works with the communities to develop and implement Community Emission Reduction Plans (CERPs). CERPs are specific to each AB 617 community and are intended to address air quality related impacts in those communities. Similarly, for the air monitoring program requirements, South Coast AQMD works with the communities to develop and deploy Community Air Monitoring Plans (CAMPs). Both the measures associated with the PM2.5 Plan and the elements of AB 617 CERPs will help reduce air pollution in disproportionately impacted areas. More detail on the AB 617 program can be found on South Coast AQMD's AB 617 Community Air Initiatives webpage.⁶

To date, there are six designated AB 617 communities in the South Coast AQMD jurisdiction. These communities are the East Los Angeles/Boyle Heights/West Commerce (ELABHWC) community, San Bernardino/Muscoy community (SBM) and Wilmington/Carson/West Long Beach community (WCWLB) designated in 2018; the Southeast Los Angeles community (SELA) and Eastern Coachella Valley (ECV) designated in 2019; and the South Los Angeles community (SLA) designated in 2020. All of these communities, with the exception of ECV are located within the South Coast Air Basin and shown in Figure 7-4.

Air Quality in Environmental Justice Communities

The impacts of air pollution are not distributed equitably throughout South Coast AQMD jurisdiction, with some communities bearing much higher air pollution burdens. In this section, results from the recently released CalEnviroScreen 4.0 are used to show the distribution of air pollution across the South Coast Air Basin.

Figure 7-5 shows levels of PM2.5 concentrations in AB 617 communities, in EJ and non-EJ areas in the South Coast Air Basin, and the overall basin-wide levels. As described in the CalEnviroScreen 4.0 report, average annual PM2.5 concentrations in each census tract were calculated using 2015-2017 ambient air monitoring data combined with satellite observations in a land-use regression model. For AB 617 communities, estimates were generated using the census tracts in each community. Boxes indicate the interquartile range (25th to 75th percentile), and the bold line indicates the median concentration (50th percentile). The two ends of the whiskers represent 1.5 multiplied by the interquartile range added and

⁶ South Coast AQMD. "AB 617 Community Air Monitoring." South Coast AQMD, <https://www.aqmd.gov/nav/about/initiatives/environmental-justice/ab617-134/ab-617-community-air-monitoring>. Accessed 2 Jan. 2024.

subtracted to the median. The dashed line represents the $12 \mu\text{g}/\text{m}^3$ standard. The dotted line represents the basin median ($11.9 \mu\text{g}/\text{m}^3$) concentration. Colors of the bars for each AB617 community correspond to map locations illustrated in Figure 7-4. While estimated annual average PM_{2.5} concentrations span a wide range of concentrations in EJ and non-EJ areas, PM_{2.5} concentrations are generally higher in EJ areas and some AB 617 communities in the South Coast Air Basin. The observed disparities within the basin are likely driven by local sources of directly emitted PM_{2.5} such as freeways and industrial facilities, that tend to be concentrated in disadvantaged communities. These sources also contribute to higher levels of diesel particulate matter, a powerful air toxic, in EJ communities.

Importantly, PM_{2.5} is one of the many air pollution challenges that these communities face. All five communities contain census tracts that rank in the CalEnviroScreen 4.0 top 25 percent most impacted tracts across California. Estimated PM_{2.5} concentrations for three EJ communities in the Basin are above the median concentration of $11.9 \mu\text{g}/\text{m}^3$ of all Basin tracts, as estimated by CalEnviroScreen.

FIGURE 7-5
ESTIMATED PM_{2.5} CONCENTRATIONS IN AB 617 COMMUNITIES (LEFT) AND SB 535-DEFINED EJ COMMUNITIES (MIDDLE) AND OVERALL PM_{2.5} CONCENTRATIONS (2021) IN THE SOUTH COAST AIR BASIN (RIGHT)

Exposure to air toxics is also an important driver of health risks in AB 617 communities. The Multiple Air Toxics Exposure Study V (MATES V)⁷ found a substantial decrease in estimated cancer risk in each of the AB 617 communities from 2012 to 2018⁸. Figure 7-6 shows the air toxic risk in the AB617 communities, and in EJ and non-EJ communities. Boxes indicate the interquartile range (25th to 75th percentile), and the bold line indicates the median concentration (50th percentile). The two ends of the whiskers represent 1.5 multiplied by the interquartile range added and subtracted to the median. Colors of the bars for the AB617 communities correspond to map locations illustrated in Figure 7-4.

FIGURE 7-6
MATES AIR TOXIC RISK IN AB 617 COMMUNITIES (LEFT) AND SB 535-DEFINED EJ COMMUNITIES (CENTER) AND OVERALL AIR TOXIC RISK IN THE SOUTH COAST AIR BASIN, PER MATES V (2021) (RIGHT)

⁷ South Coast AQMD. Multiple Air Toxics Exposure Study in South Coast AQMD. South Coast Air Quality Management District, Aug. 2021, <https://www.aqmd.gov/docs/default-source/planning/mates-v/mates-v-final-report-9-24-21.pdf?sfvrsn=6>.

⁸ South Coast AQMD. Multiple Air Toxics Exposure Study in South Coast AQMD. South Coast Air Quality Management District, Aug. 2021, <https://www.aqmd.gov/docs/default-source/planning/mates-v/mates-v-final-report-9-24-21.pdf?sfvrsn=6>.

As shown in Figure 7-6, non-EJ areas have the lowest toxics air risk as modeled in MATES V. In comparison, the median air toxic risk among AB 617 communities and EJ areas is higher than the median risk for non-EJ areas. This is likely due to these communities' proximity to air toxics sources. As shown on Figure 7-4, there is a significant toxics risk hotspot near the ports of Los Angeles and Long Beach. This is due to the activity associated with shipping, handling and transporting cargo in the region. The related activity extends up the 710 freeway, where many of the AB 617 communities are located. In addition to freeways and shipping activity, some AB 617 communities, such as Wilmington/West Long Beach/Carson, East Los Angeles/Boyle Heights/West Commerce, and Southeast LA are homes to heavy industry that contribute to higher air toxic risk. Consequently, AB 617 communities suffer the highest concentrations of cancer-causing pollutants, such as diesel particulates, due to the proximity of AB617 communities to sources of these pollutants. South Coast AQMD plans to conduct MATES VI in near future to assess the progress in air quality improvement in recent years.

Annual PM_{2.5} Attainment in AB 617 and Environmental Justice Communities

Air quality simulations to demonstrate future attainment of the PM_{2.5} standard are an integral part of the planning process to achieve clean air. These simulations evaluate the changes in PM_{2.5} concentrations over time and in response to various emissions and development scenarios. Figure 7-7 summarizes the results of the PM_{2.5} simulations in each of South Coast AQMD's AB 617 communities for the 2018, 2030 baseline, and 2030 attainment scenarios. In this analysis, model simulations were run across the entire South Coast Air Basin domain. Model results were then cropped to the boundaries illustrated in Figure 7-1 (DACs) and Figure 7-4 (AB 617 communities). Within each community, we calculated a distribution of PM_{2.5} levels in the future that would result after the implementation of the Plan. We compared these summary statistics to the 2012 annual PM_{2.5} standard of 12 µg/m³, which is marked in Figure 7-7 by the dotted line.

As shown in Figure 7-7, all AB617 communities and EJ areas have higher mean PM_{2.5} concentrations than the basin-wide average, and the maximum annual PM_{2.5} concentrations occur in EJ communities. While parts of the Basin that include portions of AB617 and EJ communities were not in attainment in 2018 and are not expected to be in attainment under the 2030 baseline conditions, all the AB 617 communities and EJ areas will attain the standard when the Plan is fully implemented.

FIGURE 7-7
MODEL-PREDICTED MEAN (TOP) AND MAXIMUM (BOTTOM) ANNUAL DESIGN VALUES IN SOUTH COAST AQMD'S AB 617 (LEFT) AND SB 535-DESIGNATED EJ AND NON-EJ COMMUNITIES (CENTER), AND BASIN-WIDE (RIGHT)

Design values are calculated under three scenarios: 2018 baseline (red), 2030 baseline (blue), and 2030 attainment (green). The dashed line represents the 12 µg/m³ standard.

Incentives and Funding in Environmental Justice Communities

Incentives and funding will continue to be a critical component in implementing the control strategies in the PM_{2.5} Plan. Among the 2022 AQMP control measures required to attain the 2015 8-hour ozone standard by 2037, this PM_{2.5} Plan included selected measures that can be implemented and achieve emission reductions prior to 2030. The 2022 AQMP commits both traditional regulatory and incentive funding-based approaches to achieve emission reductions needed to meet the federal ozone standard. Incentives and funding for EJ communities will be pursued to implement both the 2022 AQMP and this PM Plan commitments.

Incentive funding can be used to subsidize low-emitting or zero emission equipment purchases and help promote deployment of clean technologies for both stationary and mobile sources. For mobile sources, incentive funds can facilitate the replacement of older, high-emitting vehicles and equipment with the cleanest vehicles and equipment commercially available. South Coast AQMD has been implementing a

number of incentive programs to accelerate the deployment of clean technologies with a particular emphasis on benefits to EJ communities. For example, under the Lower-Emission School Bus Program, the Carl Moyer Program and other diesel mitigation programs, not less than 50 percent of the funds appropriated are expended in a manner that directly reduces air contaminants and/or associated public health risks in disadvantaged and low-income communities. Notably, programs may employ different definitions of disadvantaged in their implementation. The Lower-Emission School Bus Program allows individual agencies to develop their own individual criteria in consultation with CARB, but by default recommends uses the percentage of students in a public school district participating in the free and reduced-lunch meal program.⁹ South Coast AQMD frequently uses SB 535 to define disadvantaged communities. In their implementation of the Lower-Emission School Bus Program, they include an additional low-income criterion.¹⁰ The Carl Moyer program uses a combination of racial and ethnic composition alongside income in their definition of disadvantaged.¹¹ In implementing existing incentive programs and for the development of future programs, South Coast AQMD will continue to prioritize incentive funding in EJ areas and seek opportunities to expand funding to benefit the most disadvantaged communities, which is frequently defined using the DACs under SB535.

For stationary sources, incentives can help promote the transformation to zero emission technologies for small commercial and residential combustion sources such as water heaters and furnaces. Incentive programs will be of particular importance for measures regarding zero emission buildings. Programs to change out gas appliances, heaters and boilers may be cost-effective, but not necessarily affordable. First, there is the cost of replacing the appliances themselves – which would not be insignificant for many smaller businesses or residential households. Second, many buildings will likely need additional electrical panel upgrades and other infrastructure to support the increased electrical load needed to power the replacement appliances. These infrastructure upgrades can be far more costly than the cost of replacing gas appliances. These issues are further magnified in economically disadvantaged communities, where switching from gas to electrical appliances may be cost-prohibitive unless a substantial portion of those costs are covered by other programs.

Existing rebate programs, such as South Coast AQMD's Clear Air Furnace program, funded by Rule 1111 mitigation fees, provides rebates to those installing a residential electric heat pump to replace a natural gas furnace. In addition, a specific percentage of the funding was dedicated to those applying from a disadvantaged community. This program can be further funded to enhance the existing rebate program or expanded to include other building appliances such as water heaters. In addition, partnerships with other organizations, such as Technology and Equipment for Clean Heating (TECH) Clean California or

⁹ CARB. 2008 Lower-Emission School Bus Program Guidelines. California Air Resources Board, 15 Apr. 2008, https://ww2.arb.ca.gov/sites/default/files/2022-02/2008_LESBP_Guidelines-with-Advisories.pdf.

¹⁰ South Coast AQMD. Issue Program Announcement for Lower School Bus Emissions Program, Oct 2020. <https://www.aqmd.gov/docs/default-source/Agendas/Governing-Board/2020/2020-oct2-006.pdf?sfvrsn=2>

¹¹ Legislature, Cal. Cal. Health & Safety Code § 43023.5. https://california.public.law/codes/ca_health_and_safety_code_section_43023.5. Accessed 2 Jan. 2024.

Southern California Edison, with similar programs and directives could assist in providing more rebate money to further incentivize early deployment of cleaner technologies. Therefore, evaluating funding needs and sourcing funding to support control measures associated with zero emission building measures will be critical. But a much larger issue will be structuring incentive/rebate programs in a way that is equitable and does not leave economically disadvantaged communities behind. Stationary source control measures (BCM-01, BCM-02, BCM-03, BCM-04, ECC-02 and ECC-03, see Table 7-1) target emission reductions from residential buildings and include incentive components as part of the proposed control approach.

**TABLE 7-1
SELECTED SOUTH COAST AQMD PROPOSED STATIONARY SOURCE MEASURES**

Number	Title [Pollutant]
BCM-01	Emission Reductions from Replacement with Zero Emission or Low NOx Appliances – Residential Water Heating [PM2.5, NOx]
BCM-02	Emission Reductions from Replacement with Zero Emission or Low NOx Appliances – Residential Space Heating [PM2.5, NOx]
BCM-03	Emission Reductions from Residential Cooking Devices [PM2.5, NOx]
BCM-04	Emission Reductions from Replacement with Zero Emission or Low NOx Appliances – Residential Other Combustion Sources [PM2.5, NOx]
ECC-02	Co-benefits from Existing and Future Residential and Commercial Building Energy Efficiency Measures [All Pollutants]
ECC-03	Additional Enhancements in Reducing Existing Residential Building Energy Use [All Pollutants]

In addition, mitigation fees will be considered where appropriate under BCM-04. The mitigation fee collected would be utilized as incentives to accelerate the adoption of zero emission units or utilized to assist in panel upgrades or infrastructure at residences in disadvantaged communities. In developing these incentive programs, South Coast AQMD will seek community input and evaluate ways to prioritize distribution of funding to benefit the most disadvantaged communities. South Coast AQMD will ensure that environmental justice areas are able to access advanced technologies while benefiting from the transition to zero emission technologies.

Summary

PM2.5 air pollution and air toxics risk impact residents in the South Coast Air Basin disproportionately. EJ communities often contend with higher PM2.5 concentrations, elevated cancer risks from toxic air pollutants, and exposure to multiple pollution sources than the average levels in the Basin. The ~~Draft~~ PM2.5 Plan incorporates control measures aimed at reducing PM2.5 levels in the entire South Coast Air Basin and meeting the federal 2012 annual PM2.5 standard. These measures will help reduce air pollution in disproportionately impacted areas as well.

Efforts to address environmental injustices extend beyond the ~~Draft~~ PM2.5 Plan, with initiatives like the AB 617 program which focuses on reducing local air pollution exposure, promoting transparency, accountability, and community engagement. Collaborative partnerships, emission reduction programs, and air monitoring initiatives are integral components of AB 617, aiming to reduce air pollution and improve public health outcomes in disproportionately impacted areas.

Incentives and funding mechanisms are pivotal in facilitating the implementation of control measures, ensuring accessibility to clean technologies, and promoting the transition to zero emission solutions. South Coast AQMD is committed to prioritizing EJ areas in existing and future incentive programs, striving for equitable distribution of resources and fostering community engagement. Ongoing collaboration with impacted communities, coupled with community input and evaluation, will guide the development of inclusive incentive programs, ensuring that economically disadvantaged communities are not left behind. Moving forward, South Coast AQMD remains dedicated to addressing historic environmental injustices, improving public health, and creating a more equitable and sustainable future for all residents.

CHAPTER 8

Public Process

- PM2.5 Plan development has been a multi-agency effort including the California Air Resources Board, Southern California Association of Governments and U.S. Environmental Protection Agency.
- The PM2.5 Plan was developed through a robust and transparent process. Specific outreach efforts included:
 - Convening the AQMP Advisory Group and the Scientific, Technical, and Modeling Peer Review Advisory Group;
 - Holding regional public hearings;
 - Briefing the South Coast AQMD Mobile Source Committee and Governing Board on PM2.5 Plan development;
 - Providing meeting materials in Spanish and conducting public meetings in both English and Spanish languages; and
 - Conducting public meetings in both in-person and virtual formats, scheduled during both regular business hours and evening hours.
- Two written comments were received on the Draft PM2.5 Plan

Introduction

Development of the PM2.5 Plan has been a regional multi-agency effort including South Coast Air Quality Management District (South Coast AQMD), California Air Resource Board (CARB), Southern California Association of Governments (SCAG), U.S. EPA and other entities. Staff conducted robust public outreach efforts to engage the public and interested stakeholders, solicit feedback, and ensure transparency in the development of the Plan. The following describes specific outreach activities conducted by staff regarding the PM2.5 Plan.

Outreach Program

As a public agency, South Coast AQMD is committed to transparency and public participation during the development of State Implementation Plan (SIP) revisions. Outreach for the PM2.5 Plan aimed to achieve multiple goals including ensuring greater transparency in the process, reaching a broader and more diverse audience, and facilitating participation and engagement. The outreach program has been designed to inform the policy discussion by helping to ensure that all stakeholders have access to a common set of facts. Public awareness of federal requirements for PM2.5 SIPs and having appropriate background information are vital to engaging in a meaningful dialogue on the PM2.5 Plan.

Clean air goals cannot be achieved solely by the decisions and actions of South Coast AQMD. Stakeholder engagement is critical to the development of a successful plan. Stakeholders include community groups, businesses, environmental organizations, academia, and local, regional, state, and federal government entities. Table 8-1 lists specific stakeholder groups participating in PM2.5 Plan development.

TABLE 8-1

Advisory Group Meetings

Staff convened the AQMP and Scientific, Technical, and Modeling Peer Review (STMPR) Advisory Groups to provide feedback and recommendations on the development of the PM2.5 Plan. Advisory Group meetings were conducted in a hybrid format with in-person participation required for Advisory Group members, while members of the public were allowed to provide comment in-person or remotely. Special accommodations were offered to those with disabilities or those requiring translation. Both Advisory Groups met periodically throughout PM2.5 Plan development as shown in Table 8-2.

The AQMP Advisory Group represents a diverse cross-section of stakeholders, such as large and small businesses, labor associations, government agencies, environmental and community groups, and academia. Together, the Advisory Groups reviewed the overall aspects of the PM2.5 Plan and made recommendations concerning emissions inventories, modeling, control measures, and socioeconomic impacts, including:

- Reviewing and providing comments on: (a) studies relevant to advancing scientific and technical knowledge in support of AQMP preparation; (b) emissions inventory development and modeling approaches; (c) the development of new and revised control measures; and (d) socioeconomic data and evaluations;
- Fostering coordinated approaches toward overall attainment strategies; and
- Assisting in resolving key technical issues.

The STMPR Advisory Group consists of experts in the field of socioeconomic modeling, air quality modeling, and atmospheric science. The duties of this advisory group included reviewing and providing

feedback on air quality modeling, socioeconomic modeling techniques and making recommendations for and comments on proposed modeling approaches for attainment demonstration, precursor analysis, near-road attainment approach and emissions inventory.

TABLE 8-2
ADVISORY GROUP MEETINGS FOR THE PM2.5 PLAN

Date	Meeting

10/11/2023	STMPR Advisory Group Meeting
11/8/2023	AQMP Advisory Group Meeting

South Coast AQMD Governing Board Meetings

Before South Coast AQMD makes decisions that affect local residents and businesses, ideas and comments from the public must be considered. The opportunity to comment begins weeks prior to public workshops and ends with a public hearing by the South Coast AQMD Governing Board, where the Governing Board may vote to adopt a plan as proposed or with changes. Anyone may testify or present written comments. Holding public workshops, recording oral and written comments, responding to those comments, publishing draft plans, holding public hearings and voting publicly are all based on set procedures. Documenting the process is necessary to ensure public participation, fairness, and an accurate account to which interested parties can refer to in the future. The Governing Board meets at South Coast AQMD's Diamond Bar headquarters on the first Friday of each month. In addition, select members from the South Coast AQMD Governing Board are also members of the Mobile Source Committee, which periodically reviewed PM2.5 Plan development. South Coast AQMD released the Draft PM2.5 Plan on March 22, 2024. Table 8-3 lists the South Coast AQMD Governing Board and Mobile Source Committee meetings in which PM2.5 Plan development was or will be discussed.

TABLE 8-3
SOUTH COAST AQMD GOVERNING BOARD ACTIVITIES FOR THE PM2.5 PLAN

Date	Meeting
3/17/2023	South Coast AQMD Mobile Source Committee
10/20/2023	South Coast AQMD Mobile Source Committee
3/15/2024	South Coast AQMD Mobile Source Committee
4/5/2024	South Coast AQMD Governing Board Meeting
6/7/2024	South Coast AQMD Governing Board Meeting

Regional Public Hearings

Regional public hearings are held prior to taking a proposed plan or other significant action to the South Coast AQMD Governing Board to allow public input before Governing Board members vote on plans. Regional public hearings for the PM2.5 Plan ~~will be~~were held in April – May 2024 as shown in Table 8-4. Meeting materials for the regional public hearings ~~will be~~were translated to Spanish and ~~there will be~~one all meeting ~~hearings that features~~ were provided with live Spanish translation.

TABLE 8-4
SOUTH COAST AQMD REGIONAL PUBLIC HEARINGS SCHEDULE FOR THE PM2.5 PLAN

Date	Meeting
4/23/2024	PM2.5 Plan Regional Public Hearing – San Bernardino County
4/24/2024	PM2.5 Plan Regional Public Hearing – Riverside County
4/25/2024	PM2.5 Plan Regional Public Hearing – Orange County
5/1/2024	PM2.5 Plan Regional Public Hearing – Los Angeles County

Language Accommodations

According to the U.S. Census Bureau, almost 51% ~~percent~~of the population in the counties under South Coast AQMD jurisdiction speaks a language other than English.¹ The Spanish language is the second most common language spoken after English, where about 35% ~~percent~~of the population in the counties under South Coast AQMD jurisdiction speaks Spanish.² To facilitate greater participation and engagement of the public, including Spanish-speaking community members, South Coast AQMD staff posts a Spanish

version of meeting notices, agendas, and presentations for key public meetings on the South Coast AQMD meeting webpages. Key public meetings include Regional Public Hearings and Governing Board meetings. Live Spanish translation will be provided at these meetings. Translation services are offered upon request for all other public meetings. In addition, most meetings are conducted via videoconferencing and closed captioning is available for deaf audiences.

Written Comments and Responses to Comments

Two written comments were received on the Draft PM2.5 Plan. Responses to these comments are provided below.

Comment Letter #1

From: Dave Hall <bittermelondave@gmail.com>

Sent: Sunday, March 24, 2024 9:14 PM

To: AQMPTeam <AQMPteam@aqmd.gov>

Subject: [EXTERNAL] Draft Plan Comments-South Coast Air Basin Attainment Plan for the 2012 Annual PM2.5 Standard

Dear AQMD:

After reviewing the Environmental Justice Plan, Chapter 7 of the Draft document, I was dismayed that only a few examples of ways to reduce emissions in West Long Beach where I live were suggested. Primarily the document only focused on reducing school bus emissions in Chapter 7. Couldn't many other methods be used to reduce air pollution in the port communities and other areas with high emissions. Chapter 7 is lacking real tangible ways to address environmental justice and is cursory at best.

Respectfully,

DAVE HALL

1047 Chestnut Avenue

Long Beach, CA 90813-2921

Comment
1-1

Response to Comment 1-1: South Coast AQMD recognizes the importance of reducing pollution in port communities and has designated the area of Wilmington, Carson, and West Long Beach (WCWLB) as an AB-617 community. AB-617 is a state program that addresses the disproportionate impacts of local air pollution in disadvantaged communities. South Coast AQMD is implementing a Community Emission

Reduction Plan for WCWLB and is committed to prioritizing incentives and rulemaking efforts to reduce pollution in these communities.³

While Chapter 7 of this Plan describes air quality impacts experienced in environmental justice communities and outlines some of the steps South Coast AQMD is taking to address localized impacts, Chapter 4 and Appendix IV-A present the specific emission reduction measures that will be needed to attain the 2012 annual PM_{2.5} standard by 2030. Control measure MOB-01: Emission Reductions at Commercial Marine Ports seeks to reduce emissions from port-related sources through a rule, incentives, and/or other voluntary programs. MOB-01 seeks to reduce air pollution from some or all port-related sources (e.g., on-road heavy-duty trucks, cargo handling equipment, harbor craft, marine vessels, locomotives, and stationary equipment), to the extent that cost-effective and feasible strategies are available. The goal of this measure is to assist in achieving the committed emission reductions described in the State Implementation Plan Strategy related to on-road heavy-duty vehicles, off-road equipment, and federal and international sources that operate in and out of the Ports of Los Angeles and Long Beach. South Coast AQMD encourages all interested stakeholders to participate in the public process associated with MOB-01.⁴

May 6, 2024

Dr. Sang-Mi Lee, Planning and Rules Manager
South Coast Air Quality Management District
21865 Copley Drive
Diamond Bar, CA 91765-4178

Dear Dr. Lee,

The Ontario International Airport Authority (OIAA) has submitted this comment letter on the Draft South Coast Air Basin Attainment Plan for the 2012 Annual PM_{2.5} Standard (Draft PM_{2.5} Plan) to request that the Draft PM_{2.5} Plan be updated to accurately reflect Ontario International Airport's (ONT) forecasted aviation-related activity data and corresponding emissions.

According to the Draft PM_{2.5} Plan, the emissions inventory for all sources was derived from the emissions inventory developed for the 2022 Air Quality Management Plan (2022 AQMP).¹ The primary differences in the emissions inventories between the 2022 AQMP and the Draft PM_{2.5} Plan are: (1) the switch from EMFAC2017 to EMFAC2021 for on-road sources, and (2) a small change in construction equipment emissions for off-road sources.² As we understand it, there have been no updates to the aircraft emissions in the Draft PM_{2.5} Plan (i.e., none since the 2022 AQMP).

As discussed in our prior comment letter (dated July 5, 2022) on the then-draft 2022 AQMP, the aircraft emissions analysis in that regional planning document was not indicative of future operations at ONT. Indeed, the aircraft fleet mix

¹ South Coast Air Quality Management District. 2022. Air Quality Management Plan. <https://www.aqmd.gov/home/air-quality/air-quality-management-plans/air-quality-mgt-plan>

² The Draft PM_{2.5} Plan states that "after the development of the 2022 AQMP, an error was discovered in the emission allocations for in-use emissions from off-road construction equipment in Riverside County. This error only affected future year emissions and is now corrected in this Draft PM_{2.5} Plan."

www.flyontario.com

Page 1 of 2

Comment
2-1

used in the 2022 AQMP's analysis is not indicative of the aircraft fleet mix using ONT today. Since the aircraft emissions assumptions remain unchanged from the 2022 AQMP to the Draft PM_{2.5} Plan, the Draft PM_{2.5} Plan erroneously continues to underrepresent the potential emissions at ONT for future years.

OIAA began a review of ONT's activity forecasts in late 2021, due to the ongoing COVID recovery trends and anticipated projects at ONT. In the process of that review, OIAA discovered that aviation forecast data for ONT previously provided to AQMD was inaccurate and outdated. These inaccurate assumptions led to a significant underrepresentation of aircraft emissions for ONT in the 2022 AQMP. In order to align the Draft PM_{2.5} Plan with the anticipated future aviation-related operations at ONT, OIAA is requesting the forecast and fleet mix assumptions for ONT be updated in the Draft PM_{2.5} Plan. OIAA is happy to provide more accurate aircraft fleet mix data for ONT, both current and forecast, for your use.

OIAA looks forward to working with AQMD to resolve this issue that currently exists in the Draft PM_{2.5} Plan. We believe it is imperative that AQMD's regional plans more accurately reflect ONT's forecasted aviation activity data and related emissions for purposes of addressing both air quality issues in the South Coast Air Basin and ONT's continued ability to operate to provide important services for the benefit of the region. Please do not hesitate to contact me to facilitate further discussions on this important topic.

Sincerely,

Karen Kavanagh
Interim Chief Capital Development Officer
Ontario International Airport

Comment
2-1 Con't

Response to Comment 2-1: South Coast AQMD appreciates Ontario International Airport Authority's (OIAA) concerns regarding the aircraft emissions inventory for Ontario Airport. Please refer to response to comment 61-1 for the 2022 Air Quality Management Plan (AQMP).⁵ The 2022 AQMP aircraft emissions inventory was developed through an extensive public process that began in May 2020 and included multiple Aircraft Mobile Source Working Group Meetings. The PM2.5 Plan emissions inventory is based on that of the 2022 AQMP with only minor changes and updates reflected. Although the PM2.5 Plan does not revise the aircraft emissions inventory, South Coast AQMD anticipates that the next major emissions inventory update will occur during development of the attainment plan for the 2024 annual PM2.5 standard. OIAA is encouraged to participate in the public process for that plan and work with staff to incorporate changes in the fleet mix and growth projections at Ontario Airport.

⁵ <https://www.aqmd.gov/docs/default-source/clean-air-plans/air-quality-management-plans/2022-air-quality-management-plan/final-2022-aqmp/responses-to-comments-volume-i.pdf?sfvrsn=6>

Glossary

AAQS (Ambient Air Quality Standards): Health and welfare based standards for clean outdoor air that identify the maximum acceptable average concentrations of air pollutants during a specified period of time. (See NAAQS.)

Acute Health Effect: An adverse health effect that occurs over a relatively short period of time (e.g., minutes or hours).

Aerosol: Particles of solid or liquid matter that can remain suspended in air for long periods of time because of their small size and light weight.

Air Pollutants: Amounts of foreign and/or natural substances occurring in the atmosphere that may result in adverse effects on humans, animals, vegetation, and/or materials.

Air Quality Simulation Model: A computer program that simulates the transport, dispersion, and transformation of compounds emitted into the air and can project the relationship between emissions and air quality.

Air Toxics: A generic term referring to a harmful chemical or group of chemicals in the air. Typically, substances that are especially harmful to health, such as those considered under U.S. EPA's hazardous air pollutant program or California's AB 1807 toxic air contaminant program, are considered to be air toxics. Technically, any compound that is in the air and has the potential to produce adverse health effects is an air toxic.

Alternative Fuels: Fuels such as methanol, ethanol, hydrogen, natural gas, and liquid propane gas that are cleaner burning and help to meet mobile and stationary emission standards.

Ambient Air: The air occurring at a particular time and place outside of structures. Often used interchangeably with "outdoor" air.

ATCM (Airborne Toxic Control Measure): A type of control measure, adopted by the CARB (Health and Safety Code Section 39666 et seq.), which reduces emissions of toxic air contaminants from nonvehicular sources.

APCD (Air Pollution Control District): A county agency with authority to regulate stationary, indirect, and area sources of air pollution (e.g., power plants, highway construction, and housing developments) within a given county, and governed by a district air pollution control board composed of the elected county supervisors and in most cases, representatives of cities within the district.

AQMD (Air Quality Management District): A group or portions of counties, or an individual county specified in law with authority to regulate stationary, indirect, and area sources of air pollution within the region and governed by a regional air pollution control board comprised mostly of elected officials from within the region.

AQMP (Air Quality Management Plan): A Plan prepared by an APCD/AQMD, for a county or region designated as a nonattainment area, for the purpose of bringing the area into compliance with the requirements of the national and/or California Ambient Air Quality Standards. AQMPs designed to attain national ambient air quality standards are incorporated into the SIP.

Area-wide Sources (also known as "area" sources): Smaller sources of pollution, including permitted sources smaller than the district's emission reporting threshold and those that do not receive permits (e.g., water heaters, gas furnace, fireplaces, woodstoves, architectural coatings) that often are typically associated with homes and non-industrial sources. The California Clean Air Act requires districts to include area sources in the development and implementation of the AQMPs.

Atmosphere: The gaseous mass or envelope surrounding the earth.

Attainment Area: A geographic area which is in compliance with the National and/or California Ambient Air Quality Standards (NAAQS or CAAQS).

Attainment Plan: In general, a plan that details the emission reducing control measures and their implementation schedule necessary to attain air quality standards. In particular, the federal Clean Air Act requires attainment plans for nonattainment areas; these plans must meet several requirements, including requirements related to enforceability and adoption deadlines.

AVAPCD (Antelope Valley APCD): The Antelope Valley Air Pollution Control District.

BAAQMD (Bay Area AQMD): The San Francisco Bay Area Air Quality Management District.

BACM (Best Available Control Measure): The maximum degree of emission reduction achievable from a source or source category which is determined on a case-by-case basis, considering energy, economic and environmental impacts and other costs, which includes Best Available Control Technology. (see BACT.)

BACT (Best Available Control Technology): The most up-to-date methods, systems, techniques, and production processes available to achieve the greatest feasible emission reductions for given regulated air pollutants and processes. BACT is a requirement of NSR (New Source Review) and PSD (Prevention of Significant Deterioration). BACT as used in federal law under PSD applies to permits for sources of attainment pollutants and other regulated pollutants is defined as an emission limitation based on the maximum degree of emissions reductions allowable taking into account energy, environmental & economic impacts and other costs. [(CAA Section 169(3))]. The term BACT as used in state law means an emission limitation that will achieve the lowest achievable emission rates, which means the most stringent of either the most stringent emission limits contained in the SIP for the class or category of source, (unless it is demonstrated that the limitation is not achievable) or the most stringent emission limit achieved in practice by that class in category of source. "BACT" under state law is more stringent than federal BACT and is equivalent to federal LAER (Lowest Achievable Emissions Rate) which applies to nonattainment NSR permit actions.

BAR (Bureau of Automotive Repair): An agency of the California Department of Consumer Affairs that manages the implementation of the motor vehicle Inspection and Maintenance Program.

BARCT (Best Available Retrofit Control Technologies): an emission limitation that is based on the maximum degree of reduction achievable, taking into account environmental, energy, and economic impacts by each class or category of source.

Basin (South Coast Air Basin): Area bounded by the Pacific Ocean to the west and the San Gabriel, San Bernardino, and San Jacinto Mountains to the north and east. It includes all of Orange County and the non-desert portions of Los Angeles, Riverside, and San Bernardino Counties.

Carrying Capacity: Amount of allowable regional emissions that would still meet health-based air quality standards.

CAA (Clean Air Act): A federal law passed in 1970 and amended in 1977 and 1990 which forms the basis for the national air pollution control effort. Basic elements of the Act include national ambient air quality standards for major air pollutants, air toxics standards, acid rain control measures, and enforcement provisions.

CAAQS (California Ambient Air Quality Standards): Standards set by the State of California for the maximum levels of air pollutants which can exist in the outdoor air without unacceptable effects on human health or the public welfare, which are often more stringent than NAAQS.

CARB (California Air Resources Board): The State's lead air quality agency, consisting of a nine-member Governor-appointed board. It is responsible for attainment and maintenance of the State and federal air quality standards, and is primarily responsible for motor vehicle pollution control. It oversees county and regional air pollution management programs.

CCAA (California Clean Air Act): A California law passed in 1988 which provides the basis for air quality planning and regulation independent of federal regulations. A major element of the Act is the requirement that local APCDs/AQMDs in violation of state ambient air quality standards must prepare attainment plans which identify air quality problems, causes, trends, and actions to be taken to attain and maintain California's air quality standards by the earliest practicable date.

CEQA (California Environmental Quality Act): A California law which sets forth a process for public agencies to make informed decisions on discretionary project approvals. The process aids decision makers to determine whether any environmental impacts are associated with a proposed project. It requires significant environmental impacts associated with a proposed project to be identified, disclosed, and mitigated to the maximum extent feasible.

Chronic Health Effect: An adverse health effect which occurs over a relatively long period of time (e.g., months or years).

CMAQ (Community Multiscale Air Quality Model): A computer modeling system designed to address air quality as a whole by including state-of-the-science capabilities for modeling multiple air quality issues, including tropospheric ozone, fine particles, toxics, acid deposition, and visibility degradation.

Conformity: Conformity is a process mandated in the federal Clean Air Act to insure that federal actions do not impede attainment of the federal health standards. General conformity sets out a process that requires federal agencies to demonstrate that their actions are air quality neutral or beneficial. Transportation conformity sets out a process that requires transportation projects that receive federal funding, approvals or permits to demonstrate that their actions are air quality neutral or beneficial and meet specified emissions budgets in the SIP.

Congestion Management Program: A state mandated program (Government Code Section 65089a) that requires each county to prepare a plan to relieve congestion and reduce air pollution.

Consumer Products: Products for consumer or industrial use such as detergents, cleaning compounds, polishes, lawn and garden products, personal care products, and automotive specialty products which

are part of our everyday lives and, through consumer use, may produce air emissions which contribute to air pollution.

Contingency Measure: Contingency measures are statute-required back-up control measures to be implemented in the event of specific conditions. These conditions can include failure to meet interim milestone emission reduction targets or failure to attain the standard by the statutory attainment date. Both State and federal Clean Air Acts require that District plans include contingency measures.

CTG (Control Techniques Guidelines): Documents issued by U.S. EPA to provide recommendations for state and local air agencies on how to control the emissions of VOCs from certain types of sources in areas with smog problems. CTGs are not regulations, but they help states and areas meet the RACT requirements under the CAA. CTGs provide information on the available control technologies and their respective cost-effectiveness for reducing VOC emissions from these sources. States and areas can use the CTGs as guidance to develop their own RACT rules or standards that are appropriate for their specific circumstances.

Electric Vehicle: A motor vehicle which uses a battery-powered electric motor as the basis of its operation. Such vehicles emit virtually no air pollutants. Hybrid electric motor vehicles may operate using both electric and gasoline powered motors. Emissions from hybrid electric motor vehicles are also substantially lower than conventionally powered motor vehicles.

EMFAC: The EMISSION FACTOR model used by CARB to calculate on-road mobile vehicle emissions. The Coachella Valley Contingency Measure SIP Revision is based on the version of EMFAC2017.

Emission Inventory: An estimate of the amount of pollutants emitted from mobile and stationary sources into the atmosphere over a specific period such as a day or a year.

Emission Offset (also known as an emission trade-off): A regulatory requirement whereby approval of a new or modified stationary source of air pollution is conditional on the reduction of emissions from other existing stationary sources of air pollution or banked reductions. These reductions are required in addition to reductions required by BACT.

Emission Standard: The maximum amount of a pollutant that is allowed to be discharged from a polluting source such as an automobile or smoke stack.

FIP (Federal Implementation Plan): In the absence of an approved State Implementation Plan (SIP), a plan prepared by the U.S. EPA which provides measures that nonattainment areas must take to meet the requirements of the Federal Clean Air Act.

Fugitive Dust: Dust particles which are introduced into the air through certain activities such as soil cultivation, off-road vehicles, or any vehicles operating on open fields or dirt roadways.

Goods Movement: An event that causes movement of commercial materials or stock typically at ports, airports, railways, highways, including dedicated truck lanes and logistics centers.

GHGs (Greenhouse Gases): A gas in an atmosphere that absorbs long-wave radiant energy reflected by the earth, which warms the atmosphere. GHGs also radiate long-wave radiation both upward to space and back down toward the surface of the earth. The downward part of this long-wave radiation absorbed by the atmosphere is known as the “greenhouse effect.”

HEV (Hybrid Electric Vehicles): Hybrids commercially available today combine an internal combustion engine with a battery and electric motor.

Hydrocarbon: Any of a large number of compounds containing various combinations of hydrogen and carbon atoms. They may be emitted into the air as a result of fossil fuel combustion, fuel volatilization, and solvent use, and are a major contributor to smog. (Also see VOCs.)

HFCV (Hydrogen Fuel Cell Vehicles): Vehicles that produce zero tailpipe emissions and run on compressed hydrogen fed into a fuel cell "stack" that produces electricity to power the vehicle.

ICAPCD (Imperial County APCD): The County of Imperial Air Pollution Control District.

Incentives: Tax credits, financial rebates/discounts, or non-monetary conveniences offered to encourage further use of advanced technology and alternative fuels for stationary and mobile sources.

Indirect Source: Any facility, building, structure, or installation, or combination thereof, which generates or attracts mobile source activity that results in emissions of any pollutant (or precursor). Examples of indirect sources include employment sites, shopping centers, sports facilities, housing developments, airports, commercial and industrial development, and parking lots and garages.

Indirect Source Control Program: Rules, regulations, local ordinances and land use controls, and other regulatory strategies of air pollution control districts or local governments used to control or reduce emissions associated with new and existing indirect sources.

Inspection and Maintenance Program: A motor vehicle inspection program implemented by the BAR. It is designed to identify vehicles in need of maintenance and to assure the effectiveness of their emission control systems on a biennial basis. Enacted in 1979 and strengthened in 1990. (Also known as the "Smog Check" program.)

LAER (Lowest Achievable Emission Rate): The more stringent rate of emissions for any source based on the following: the most stringent emissions limitation in which is contained in the implementation plan of any State for such class or category of sources, unless the owner or operator of the proposed source demonstrates that such limitations are not achievable; or the most stringent emissions limitation which is achieved in practice by such class or category of stationary sources. This limitation, when applied to a modification, means the lowest achievable emissions rate for the new or modified emissions units within or stationary source. In no event shall the application of this term permit a proposed new or modified source to emit any pollutant in excess of the amount allowable under applicable new source standards of performance.

LEV (Low Emission Vehicle): A vehicle which is certified to meet the CARB 1994 emission standards for low emission vehicles.

Low NO_x Technologies: Refers to NO_x emissions approaching zero and will be delineated for individual source categories through the process of developing the Air Quality Management Plan/State Implementation Plan and subsequent control measures.

Maintenance Plan: In general, a plan that details the actions necessary to maintain air quality standards. In particular, the federal Clean Air Act requires maintenance plans for areas that have been redesignated as attainment areas.

MCAQD (Maricopa County Air Quality Department): The Maricopa County Air Quality Department in Arizona.

MDAQMD (Mojave Desert AQMD): The Mojave Desert Air Quality Management District.

Mobile Sources: Moving sources of air pollution such as automobiles, motorcycles, trucks, off-road vehicles, boats and airplanes.

Model Year: Model year refers to the actual annual production period (year) as determined by the manufacturer.

MSM (Most Stringent Measures): The maximum degree of emission reduction that has been required or achieved from a source or source category in any other attainment plans or in practice in any other states and that can feasibly be implemented in the area seeking the extension. "Serious" nonattainment areas can request an extension of the attainment date under CAA Section 188(e) and are required to demonstrate that the attainment plan includes the MSM. In some cases it may be possible for the MSM requirement to result in no more controls and no more emissions reductions in an area than result from the implementation of BACM and BACT.

MVEB (Motor Vehicle Emissions Budget): The portion of the total allowable emissions allocated to highway and transit vehicles and is defined in the SIP for the purpose of demonstrating Reasonable Further Progress (RFP) for interim milestone years and attainment of the NAAQS.

NAAQS (National Ambient Air Quality Standards): Standards set by the federal U.S. EPA for the maximum levels of air pollutants which can exist in the outdoor air without unacceptable effects on human health or the public welfare.

NOx (Nitrogen Oxides, Oxides of Nitrogen): A general term pertaining to compounds of nitric acid (NO), nitrogen dioxide (NO₂), and other oxides of nitrogen. Nitrogen oxides are typically created during combustion processes, and are major contributors to smog formation and acid deposition. NO₂ is a criteria air pollutant, and may result in numerous adverse health effects; it absorbs blue light, resulting in a brownish-red cast to the atmosphere and reduced visibility.

Nonattainment Area: A geographic area identified by the U.S. EPA and/or CARB as not meeting either NAAQS or CAAQS for a given pollutant.

NSR (New Source Review): A program used in development of permits for new or modified industrial facilities which are in a nonattainment area, and which emit nonattainment criteria air pollutants. The two major requirements of NSR are Best Available Control Technology and Emission Offsets.

Ozone: A strong smelling reactive toxic chemical gas consisting of three oxygen atoms. It is a product of the photochemical process involving the sun's energy. Ozone exists in the upper atmosphere ozone layer as well as at the earth's surface. Ozone at the earth's surface causes numerous adverse health effects and is a criteria air pollutant. It is a major component of smog.

Ozone Precursors: Chemicals such as hydrocarbons and oxides of nitrogen, occurring either naturally or as a result of human activities, which contribute to the formation of ozone, a major component of smog.

PCAPCD (Placer County APCD): The County of Placer Air Pollution Control District.

Permit: Written authorization from a government agency (e.g., an air quality management district) that allows for the construction and/or operation of an emissions generating facility or its equipment within certain specified limits.

PEV (Plug-in Electric Vehicle): Vehicles that can be recharged from any external source of electricity and the electricity is stored in a rechargeable battery pack to drive or contribute to drive the wheels.

PHEV (Plug-in Hybrid Electric Vehicle): Vehicles similar to traditional hybrids but are also equipped with a larger, more advanced battery that allows the vehicle to be plugged in and recharged in addition to refueling with gasoline. This larger battery allows the car to drive on battery alone, gasoline alone, or a combination of electric and gasoline fuels.

PM (Particulate Matter): Solid or liquid particles of soot, dust, smoke, fumes, and aerosols.

PM Precursors: Chemicals such as volatile organic compounds, oxides of nitrogen, and ammonia, occurring either naturally or as a result of human activities, which contribute to the formation of particulate matter.

PM₁₀ (Particulate Matter less than 10 microns): A major air pollutant consisting of tiny solid or liquid particles of soot, dust, smoke, fumes, and aerosols. The size of the particles (10 microns or smaller, about 0.0004 inches or less) allows them to easily enter the air sacs in the lungs where they may be deposited, resulting in adverse health effects. PM₁₀ also causes visibility reduction and is a criteria air pollutant.

PM_{2.5} (Particulate Matter less than 2.5 microns): A major air pollutant consisting of tiny solid or liquid particles, generally soot and aerosols. The size of the particles (2.5 microns or smaller, about 0.0001 inches or less) allows them to easily enter the air sacs deep in the lungs where they may cause adverse health effects, as noted in several recent studies. PM_{2.5} also causes visibility reduction and is a criteria air pollutant.

PSD (Prevention of Significant Deterioration): A program used in development of permits for new or modified industrial facilities in an area that is already in attainment. The intent is to prevent an attainment area from becoming a nonattainment area. This program, like require BACT as defined in the Clean Air Act and, if an AAQS is projected to be exceeded, Emission Offsets.

Public Consultation: A consultation held by a public agency for the purpose of informing the public and obtaining its input on the development of a regulatory action or control measure by that agency.

Public Workshop: A workshop held by a public agency for the purpose of informing the public and obtaining its input on the development of a regulatory action or control measure by that agency.

PZEV (Partial Zero Emission Vehicle): A vehicle emissions rating within California's exhaust emission standards. Cars that are certified as PZEVs meets the Super Ultra Low Emission Vehicle exhaust emission standard and has zero evaporative emissions from its fuel system.

RACM (Reasonably Available Control Measures): An area-specific analysis focusing on area, mobile and non-major point sources. It considers measures that are readily implemented, are economically and technologically feasible, and contribute to the advancement of attainment in a manner that is "as expeditious as practicable."

RACT (Reasonably Available Control Technology): The lowest emission limitation that a particular source is capable of meeting by the application of control technology that is reasonably available considering technological and economic feasibility.

RFP (Reasonable Further Progress): Annual incremental reductions in emissions of the relevant air pollutant as are required by this part or may reasonably be required by the Administrator for the purpose of ensuring attainment of the applicable national ambient air quality standard by the applicable date, as defined in CAA Section 171(1). The goal of the RFP requirements is for areas to achieve generally linear progress toward attainment. To determine RFP for the attainment date, EPA guidance states that the plan should rely only on emission reductions achieved from sources within the nonattainment area.

RTP (Regional Transportation Plan): The long-range transportation plan developed by the Southern California Association of Governments that provides a vision for transportation investments throughout the South Coast region. The RTP considers the role of transportation in the broader context of economic, mobility, environmental, and quality-of-life goals for the future, identifying regional transportation strategies to address regional mobility needs.

SBCAPCD (Santa Barbara County APCD): The County of Santa Barbara Air Pollution Control District.

SCM (Suggested Control Measure): A model rule developed by CARB that local air districts can adopt for their architectural coatings rule. The SCM was last updated in 2020.

SCS (Sustainable Communities Strategy): Planning element in the RTP that integrates land use and transportation strategies that will achieve CARB's GHG emissions reduction targets.

SDAPCD (San Diego County APCD): The County of San Diego Air Pollution Control District.

SIP (State Implementation Plan): A document prepared by each state describing existing air quality conditions and measures which will be taken to attain and maintain national ambient air quality standards. (see AQMP.)

SJVAPCD (San Joaquin Valley APCD): The San Joaquin Valley Air Pollution Control District.

SMAQMD (Sacramento Metro AQMD): The Sacramento Metropolitan Air Quality Management District.

Smog: A combination of smoke, ozone, hydrocarbons, nitrogen oxides, and other chemically reactive compounds which, under certain conditions of weather and sunlight, may result in a murky brown haze that causes adverse health effects. The primary source of smog in California is motor vehicles. (See Inspection and Maintenance Program.)

Smoke: A form of air pollution consisting primarily of particulate matter (i.e., particles). Other components of smoke include gaseous air pollutants such as hydrocarbons, oxides of nitrogen, and carbon monoxide. Sources of smoke may include fossil fuel combustion, agricultural burning, and other combustion processes.

SO₂ (Sulfur Dioxide): A strong smelling, colorless gas that is formed by the combustion of fossil fuels. Ocean-going vessels, which may use oil high in sulfur content, can be major sources of SO₂. SO₂ and other sulfur oxides contribute to ambient PM_{2.5}. SO₂ is also a criteria pollutant.

SSAB (Salton Sea Air Basin): Area comprised of a central portion of Riverside County (the Coachella Valley) and Imperial County. The Riverside County portion of the SSAB is bounded by the San Jacinto Mountains in the west and spans eastward up to the Palo Verde Valley.

Stationary Sources: Non-mobile sources such as power plants, refineries, and manufacturing facilities which emit air pollutants; can include area sources depending on context.

SULEV (Super Ultra Low Emission Vehicle): A vehicle emissions rating within California's LEV 1 and LEV 2 exhaust emission standards.

TAC (Toxic Air Contaminant): An air pollutant, identified in regulation by the CARB, which may cause or contribute to an increase in deaths or in serious illness, or which may pose a present or potential hazard to human health. TACs are considered under a different regulatory process (California Health and Safety Code Section 39650 et seq.) than pollutants subject to CAAQS. Health effects due to TACs may occur at extremely low levels, and it is typically difficult to identify levels of exposure which do not produce adverse health effects.

TCM (Transportation Control Measure): Under Health & Safety Code Section 40717, any control measure to reduce vehicle trips, vehicle use, vehicle miles traveled, vehicle idling, or traffic congestion for the purpose of reducing motor vehicle emissions. TCMs can include encouraging the use of carpools and mass transit. Under federal law, includes, but is not limited to those measures listed in CAA Section 108(f).

UFP (Ultrafine Particles): Particles with a diameter less than 0.1 mm (or 100 nm).

ULEV (Ultra Low Emission Vehicle): Vehicles with low emission ratings within California's LEV 1 or LEV 2 exhaust emission standards. The LEV 1 emission standards typically apply to cars from 1994–2003. The LEV 2 emission standards were adopted in 1998 and typically apply to cars from 2004–2010.

U.S. EPA (United States Environmental Protection Agency): The federal agency charged with setting policy and guidelines, and carrying out legal mandates for the protection of national interests in environmental resources.

VCAPCD (Ventura County APCD): The Ventura County Air Pollution Control District.

VMT (Vehicle Miles Traveled): Total vehicle miles traveled by all or a subset of mobile sources.

VOCs (Volatile Organic Compounds): Hydrocarbon compounds that exist in the ambient air. VOCs contribute to the formation of smog and/or may themselves be toxic. VOCs often have an odor, and some examples include gasoline, alcohol, and the solvents used in paints.

Zero Emission Technologies: Advanced technology or control equipment that generates zero end-use emissions from stationary or mobile source applications.

ZEV (Zero Emission Vehicle): A vehicle that produces no emissions from the on-board source of power.

SOUTH COAST AQMD

REGIONAL PUBLIC HEARING FOR

SOUTH COAST AIR BASIN ATTAINMENT PLAN

FOR THE 2012 ANNUAL PM2.5 STANDARD

APRIL 23, 2024

1 IAN MacMILLAN: Good morning, everybody. We'll
2 get started in just a couple minutes here.

3 Okay. Good morning, everybody. My name is Ian
4 MacMillan. I'm an assistant deputy executive officer in
5 the Planning Division here at South Coast AQMD.

6 Before we get started today, I just want to go
7 through some housekeeping remarks. This is something
8 that we do before every meeting.

9 So again, good morning. Thank you for
10 participating in the first of four regional public
11 hearings for the PM2.5 Plan. This first meeting is
12 focused on San Bernardino County. We're going to do our
13 best to facilitate a smooth meeting with public
14 participation. We have two formats for participation.
15 The Zoom web application as well as teleconference.

16 Before we begin, I want to review some
17 guidelines and general instructions for the meeting.

18 First, please silence your other communication
19 devices such as your cell or desk phone. This will
20 ensure that we're not hearing any feedback or causing
21 interruption during the meeting. This meeting is being
22 translated in Spanish. To watch or listen to this
23 meeting in the language of your choice, click on the
24 globe icon labeled "Interpretation" at the bottom of
25 your screen. From there, select the language of your

Audio Transcription

1 choice. After you select your language, if you hear
2 both languages at the same time, please click "Mute
3 original audio."

4 For those participating by phone, if you wish
5 to hear the meeting in Spanish, please use the phone
6 number and meeting I.D. number posted on the agenda.
7 I'm going to pause right now for the translators to come
8 in and repeat some of this relevant information.

9 (Translator speaking in Spanish.)

10 IAN MacMILLAN: Thank you.

11 Okay. So to continue, all participants on
12 Zoom, except for panelists, will be placed on mute by
13 the host. You will not be able to mute or unmute your
14 line manually.

15 After each agenda item, I will ask if there are
16 any clarifying questions, but we would like to reserve
17 public comments for the end of the meeting after all
18 presentations.

19 For those on Zoom, if you would like to make
20 public comment on the Zoom screen, please click on the
21 raise hand button. For those calling in by phone, you
22 can dial star 9 to signal you would like to comment.
23 Your name or part of your phone number will be called
24 when it is your turn to comment, and the host will
25 unmute your line automatically.

Audio Transcription

1 Please note you can hang up and/or leave the
2 Zoom meeting at any time. As always, please treat
3 others with courtesy, civility, and respect. Failure to
4 do so can result in your mic being muted or you being
5 dropped from the meeting.

6 Lastly, please be aware that this video
7 conference meeting is being recorded. By participating
8 in this meeting hosted by South Coast AQMD, you agree to
9 authorize recording of audio and visual content
10 presented during the live event and consent to
11 subsequent use of the recording in the public domain by
12 South Coast AQMD.

13 At this time I'll ask if there are any board
14 members or board member consultants who would like to be
15 placed on the panel, please raise your hand and staff
16 will move you over.

17 And then finally, as far as introductions, I'll
18 ask every presenter to introduce themselves as they --
19 right before they give their presentation.

20 With that, let's go ahead and get started. We
21 have four presentations today to go through. So let's
22 go ahead and get started.

23 The first one is going to be an overview of the
24 PM2.5 Plan itself.

25 And, Eric, if you want to go ahead, take it

Audio Transcription

1 away.

2 ERIC PRASKE: Thanks, Ian. I'll just wait for
3 the slides to come up here.

4 All right. So I'm Eric Praske. I supervise
5 the State Implementation Plan development here at South
6 Coast AQMD. And as Ian mentioned, I'll be presenting a
7 general overview of the South Coast Air Basin Attainment
8 Plan for the 2012 Annual PM2.5 Standard.

9 Next slide, please.

10 So the South Coast Air Quality Management
11 District is the local air pollution control agency
12 responsible for the South Coast Air Basin and Coachella
13 Valley. Our jurisdiction encompasses all of Orange
14 County as well as portions of L.A., San Bernardino, and
15 Riverside counties. We are the largest of 35 local air
16 agencies in California as well as across the rest of the
17 nation, and over 17 million residents are in our
18 jurisdiction.

19 In terms of responsibilities, we regulate
20 emissions primarily from stationary sources with limited
21 authority over mobile sources. We develop and implement
22 plans to meet national air quality standards. We permit
23 and inspect over 28,000 businesses and administer over
24 \$100 million of incentive funding annually.

25 Next slide, please.

Audio Transcription

1 So as many of you are likely aware, our region
2 has historically suffered from some of the worst air
3 quality in the United States. Despite significant
4 process that's been made over the past several decades,
5 our residents still suffer from breathing the worst
6 ozone in the nation and among the worst fine particulate
7 matter, or PM2.5 levels in the nation.

8 Next slide, please.

9 In this presentation I'll be providing
10 background on PM2.5 as well as air quality trends in the
11 South Coast Air Basin. Next I'll discuss the proposed
12 control strategy to meet the 2012 annual PM2.5 Standard.
13 Then I'll be providing an overview on the attainment
14 demonstration; essentially how we demonstrate the
15 implementation of that control strategy will lead us
16 into attainment. And then I'll be discussing --
17 wrapping up with next steps and the public process.

18 Next slide, please.

19 So PM2.5 is defined as particulate matter less
20 than 2.5 microns in diameter. This is very small. It's
21 so small in fact that you can't see PM2.5. By
22 comparison, a fine grain of beach sand is about 90
23 microns in diameter, and the width of a human hair is
24 about 50 to 70 microns. And because PM2.5 is so small,
25 it is able to penetrate our body's defenses, end up deep

Audio Transcription

1 in our lungs, and then eventually cross over into the
2 bloodstream and even cross the blood-brain barrier.

3 So because it is able to penetrate our body's
4 defenses, it is linked to a number of very serious
5 health effects, including premature death, asthma, and
6 lung cancer. There's even evidence to link it to
7 metabolic diseases, cognitive diseases such as
8 Alzheimer's disease. And because exposure to PM2.5 is
9 so toxic, it actually drives the majority of public
10 health costs due to air pollution in our region.

11 Next slide, please.

12 So as the title of the presentation suggested,
13 I'll be discussing the 2012 Annual PM2.5 Standard. The
14 level of that standard is 12 micrograms per cubic meter.
15 The South Coast Air Basin is classified as a serious
16 non-attainment area with an attainment date of December
17 2025. There are also a few other PM2.5 standards that
18 I'll go over just briefly for information purposes.

19 So there's the 1997 annual standard at
20 15 micrograms per cubic meter. The South Coast Air
21 Basin attains this standard; it actually has attained
22 the standard since 2013. In addition, there's the 2006
23 24-hour standard at 35 micrograms per cubic meter.
24 We're also in serious non-attainment of this standard
25 with an attainment date of December of last year.

Audio Transcription

1 Some good news, we actually have reviewed the
2 monitoring data from last year, and we believe that we
3 met the standard by the attainment date.

4 And then some of you may have heard of a new
5 PM2.5 Standard that EPA recently set; that's the 2024
6 annual PM2.5 Standard. They lowered the level from 12
7 down to 9 micrograms per cubic meter.

8 We currently don't have any planning
9 requirements for this standard; however, we do expect
10 that EPA will designate us as a non-attainment area in
11 2026. And as far as the attainment plan goes, we would
12 likely be looking at an attainment date in 2036 with a
13 potential to extend to 2041.

14 Next slide, please.

15 So this graph is showing the trend in PM2.5
16 levels in the South Coast Air Basin over the past two
17 decades. As you can see, clearly significant progress
18 has been made, however, there has been a bit of a
19 leveling off over the past several years. Shown in the
20 horizontal lines are the levels of the various annual
21 PM2.5 standards. So there's the 1997 standard. Recall
22 that I mentioned we're in attainment of this standard,
23 so our levels are below that line. And then the subject
24 of today's presentation, the 2012 standard, is shown in
25 the orange line. And right now we're about 2 micrograms

Audio Transcription

1 per cubic meter over that standard, 1.5 to 2 micrograms
2 per cubic meter over.

3 And then there is the 2024 standard shown in
4 the dashed yellow line. And as is evident from this
5 graph, we have a significant ways to go to meet that
6 standard. We'll encounter substantial challenges
7 associated with that, as will many other air districts
8 throughout California as well as across the rest of the
9 nation.

10 Next slide, please.

11 Okay. So I'll be discussing the 2012 PM2.5
12 Standard in today's presentation.

13 For PM2.5 there are two classifications for
14 non-attainment areas. There's moderate and serious.
15 And the South Coast Air Basin is in serious
16 non-attainment. Essentially what that means is it
17 allows us the most amount of time to meet the standard.

18 The Coachella Valley is in attainment of the
19 2012 PM2.5 standards, so I won't be discussing Coachella
20 Valley in this presentation.

21 Next slide.

22 So South Coast AQMD initially developed an
23 attainment plan for the 2012 PM2.5 Standard as part of
24 the 2016 Air Quality Management Plan. The 2016 AQMP was
25 submitted to EPA in 2017; however, EPA did not act on

Audio Transcription

1 that plan for several years, and during that time some
2 new monitoring data at near-road monitors became
3 available and eligible for consideration and attainment
4 demonstration starting in 2020. So when EPA finally got
5 around to acting on our plan in December of 2020, they
6 requested a supplemental attainment demonstration for
7 these near-road monitors.

8 Due to challenges and concerns associated with
9 the near-road monitors, the submitted plan was withdrawn
10 in 2023 to avoid potential disapproval by EPA. That
11 withdrawal triggered the need to develop a revised
12 attainment plan, and that plan needs to be submitted to
13 EPA before December of this year to avoid stationary
14 source permitting sanctions.

15 Next slide, please.

16 So the proposed control strategy to attain the
17 2012 PM_{2.5} Standard is based on the continued
18 implementation of the control measures to reduce ozone
19 that were adopted as part of the 2022 Air Quality
20 Management Plan. In addition we are required to satisfy
21 EPA stringency requirements, and so there are some
22 limited new control measures to reduce direct PM_{2.5} as
23 well as ammonia emissions, and those are included in
24 this plan.

25 Next slide, please.

Audio Transcription

1 So the measures from the 2022 AQMP, just a
2 broad overview of them, so we have the stationary source
3 measures which seek to transition to zero emission
4 wherever feasible while allowing the lowest alternative
5 emission source technology wherever zero emission is
6 infeasible. We are also proposing to include our mobile
7 source incentive measures and facility-based mobile
8 source measures. In the next presentation you'll be
9 hearing from CARB about the specific measures that
10 they'll be continuing to implement as part of the State
11 SIP Strategy.

12 Next slide, please.

13 So I mentioned EPA stringency requirements.
14 Chief among those is that of Most Stringent Measures, or
15 MSM, the reason we need to implement MSM in this plan is
16 because we are requesting a five-year extension of the
17 attainment date. So recall from earlier that the
18 current statutory serious attainment date is set
19 December 2025. We're requesting a five-year extension
20 as part of this plan to demonstrate attainment by 2030.

21 So MSM is a requirement that we demonstrate
22 that our rules are at least as stringent as those in any
23 other air district or state. And so as part of the MSM
24 analysis we developed four measures that will need to be
25 implemented by December 2029.

Audio Transcription

1 The first measure involves Rule 445. This is
2 our Check Before You Burn program. We are proposing to
3 remove the low income exemption while retaining the sole
4 source of heat exemption.

5 Next is -- our next MSM is Rule 1138. This is
6 our commercial cooking rule. We are proposing to lower
7 the threshold to require catalytic oxidizers for
8 chain-driven charbroilers.

9 The third measure involves Rule 223. This is a
10 permitting rule for large, contained animal facilities,
11 and we are proposing to lower the thresholds for dairy
12 and poultry farms to match the thresholds in
13 San Joaquin Valley.

14 The fourth measure is to require composting of
15 chipped and ground green waste prior to land
16 application.

17 Next slide, please.

18 Okay. So now I'll segue into the attainment
19 demonstration component of this presentation, but first
20 a little bit of background or what an attainment
21 demonstration is and how we conduct the attainment
22 demonstration.

23 So we begin by developing a comprehensive
24 emissions inventory of all stationary and mobile sources
25 in our jurisdiction. We then feed those emissions into

Audio Transcription

1 our air quality model which is able to simulate PM2.5
2 concentrations. And so we run this process for a base
3 year. In this case the base year is 2018.

4 Then we develop a control strategy for our
5 attainment year. So that would be 2030 in the case of
6 this plan. And so we apply those controls to select
7 sources in the emissions inventory, and then we rerun
8 the air quality model with those reduced emissions and
9 we look at essentially the change in PM2.5 levels from
10 the base to the future year and we use that ratio and
11 apply it to the base year PM2.5 levels to project future
12 air quality.

13 Next slide, please.

14 So here you can see that our control strategy
15 is calling for a 54 percent reduction in NOx emissions
16 from 2018 to our 2030 attainment year. In addition, we
17 will be reducing PM2.5 emissions by about 3 tons per
18 year -- 3 tons per day between 2018 and 2030. And so
19 when we run our air quality model with these 2030
20 attainment scenario emissions, we are able to
21 demonstrate attainment at all locations across the
22 South Coast Air Basin.

23 Next slide, please.

24 So here we're seeing the base year, 2018 design
25 values at monitors that exceed the 2012 annual PM2.5

Audio Transcription

1 Standard. The highest standard is on -- the highest
2 measured design value or level of PM2.5 is at the
3 Ontario near-road monitor at 14 micrograms per cubic
4 meter. This is actually -- this is a measured design
5 value.

6 And then recall that we apply the ratio from
7 the air quality model of the future to the base year
8 projected air quality, and then we're able to determine
9 and apply that ratio to the level to determine whether
10 we'll be in attainment of the standard. And so when we
11 do that we will actually come out with a design value of
12 11.6 micrograms per cubic meter at the Ontario near-road
13 monitor well in attainment of the 2012 PM2.5 Standard.

14 The next highest site in the 2018 base year is
15 Mira Loma at 13.5 micrograms per cubic meter. Mira Loma
16 is expected to be in attainment by 2030 with a design
17 value at 12 micrograms per cubic meter.

18 So shown here are the other monitors that
19 exceeded the standard in the base year. So Long Beach
20 near road, Compton, and Riverside. And all of these
21 monitors are expected to be in attainment by 2030.

22 Next slide, please.

23 So we began the process to develop this plan in
24 spring of last year when we convened our advisor groups.
25 Those advisor groups met periodically between spring and

Audio Transcription

1 fall. We then continued to develop the draft plan, and
2 we actually just released the draft plan on March 22nd
3 for public review and comment. We're currently in the
4 public review stage for the plan, and that's why we're
5 hold our regional public hearings. Within another week
6 or so we'll be releasing the Draft Socioeconomic Impact
7 Assessment.

8 And then the public hearing for board
9 consideration of the PM2.5 Plan will be held on
10 June 7th. Should the board choose to adopt the PM2.5
11 Plan, it will be submitted to CARB for approval and
12 subsequent transmittal to EPA for incorporation into the
13 State Implementation Plan.

14 Next slide.

15 Okay. So there's -- recall there's the new
16 2024 annual PM2.5 Standard in which EPA lowered the
17 level from 12 to 9 micrograms per cubic meter. We are
18 expecting that the South Coast Air Basin will be
19 designated as a non-attainment area in 2026, and we will
20 be looking at an attainment year of 2036 with the
21 potential to request an extension to 2041. That plan
22 will need to be adopted and submitted to EPA by August
23 of 2027.

24 We do know that the AQMP NOx strategy, the 2022
25 AQMP NOx strategy alone will not be sufficient to meet

Audio Transcription

1 this standard, and achieving the new standard will
2 require substantial additional controls, especially on
3 direct PM2.5 sources.

4 Next slide, please.

5 So as Ian mentioned, we have four regional
6 public hearings. We're currently holding the first
7 hearing for San Bernardino County. Tomorrow we will be
8 switching to an in-person format at CARB headquarters in
9 Riverside. Then we will be going back to the virtual
10 format for Orange County on Thursday. And next
11 Wednesday we will be at the Dollarhide Community Center
12 in Compton for the L.A. County public hearing.

13 Next slide, please.

14 All supporting documents as well as this
15 presentation and PM2.5 Plan chapters and appendices are
16 available on our web site. You can also point your
17 camera here at the QR code to be taken directly to that
18 site.

19 Next slide, please.

20 So the written comment deadline for the PM2.5
21 Plan is Tuesday, May 7th. You can submit all written
22 comments via e-mail to AQMPteam@AQMD.gov. If you have
23 specific inquiries related to PM2.5 Plan, please contact
24 Dr. Sang-Mi Lee, and for inquiries specific to CEQA and
25 socioeconomic impacts, please contact Barbara Radlein.

Audio Transcription

1 Next slide, please.

2 So the PM2.5 Plan in summary, the PM2.5 Plan
3 has been developed to demonstrate attainment of the 2012
4 PM2.5 Standard in the South Coast Air Basin by 2030.
5 The PM2.5 Plan is based on continued implementation of
6 the 2022 AQMP NOx strategy with limited additional
7 controls to satisfy EPA stringency requirements. The
8 public hearing will be on June 7th. And obviously we'll
9 need to be developing a new plan for the -- to attain
10 the 2024 PM2.5 Standard.

11 Next slide, please.

12 All right. So we encourage you to sign up for
13 our newsletter at the web site shown here, and make sure
14 to tic the box for AQMP/SIP interested parties.

15 That concludes my presentation, and I'll hand
16 it back over to Ian.

17 IAN MacMILLAN: Hey there, everybody. I
18 apologize for that. My Zoom just quit. I apologize.
19 Hopefully, can everybody hear me?

20 ERIC PRASKE: We can hear you, Ian.

21 IAN MacMILLAN: Okay. I'm sorry about that.

22 So the question I think was from Mary V. asking
23 about San Bernardino data. We did show some data on one
24 of the slides, and here -- no, I think we were just
25 showing some of the key sites that are important for

Audio Transcription

1 this PM2.5 Plan. But within the plan itself there's a
2 lot more information about all the sites that we collect
3 PM2.5 data as well as on our web site. So we can
4 provide some more information on that. Feel free to
5 reach out to us if there are any further questions
6 there.

7 For now, we're going to go ahead and move on to
8 our next presentation. This is going to be from CARB.

9 And so, Ariel, if you're available, feel free
10 to introduce yourself and take it away.

11 ARIEL FIDELDY: Thanks, Ian.

12 Hi, everybody. Yeah, while we're bring up the
13 slides, I'll just say my name is Ariel Fideldy. I am a
14 manager at the California Air Resources Board over the
15 team that works really closely with South Coast on
16 developing SIPs and the control strategies that are
17 needed. At the state level, my team does lead our
18 development, what is known as the State SIP Strategy.
19 So I will be walking through today, once we get the
20 slides up, kind of the CARB side of the control strategy
21 that's going into this PM2.5 Plan.

22 All right. Why don't you go ahead, next slide,
23 please.

24 Thank you.

25 So like AQMD, CARB's reductions in the PM2.5

Audio Transcription

1 Plan are based on measures in our 2022 State SIP
2 Strategy which was focused on the 70 parts per billion
3 ozone standard. This strategy that we developed over a
4 few years through a robust public process, it identified
5 the level of action needed to meet air quality standards
6 and improve public health. It was, you know, really a
7 document that identified a bunch of new control measures
8 from CARB that are going to be driving the pace and
9 scale of our rule makings at CARB through the end of
10 this decade really.

11 Our board approved the state measure
12 commitments that were in that document, the State SIP
13 Strategy, in September of 2022. And this strategy is
14 what we've utilized for the PM plan. We've basically
15 taken these measures, estimated the emission reductions
16 in 2030 that can help support attainment of the PM2.5
17 Standard.

18 Next slide.

19 This figure here identifies the list of these
20 measures that CARB is pursuing, you know, included in
21 the State SIP Strategy, but these are the ones
22 specifically that are going to support attainment of the
23 PM2.5 Standard in the South Coast. Some of the measures
24 on this slide, they have already been adopted as
25 regulations by the CARB board. Those are the ones that

Audio Transcription

1 are identified with the asterisk on the slide here.

2 Specifically I want to mention our Advanced
3 Clean Fleets and in use locomotive regulations. Those
4 programs were both adopted last year and they were
5 really monumental regulation, of course, first of their
6 kind. Our Advanced Clean Fleets regulation, you know,
7 is going to require fleets, heavy duty truck fleets
8 specifically to turn over to zero emission vehicles over
9 the next decade. And the in use locomotive regulation
10 sets in use requirements, but it uses mechanisms under
11 our available authority to accelerate the adoption of
12 advanced cleaner locomotive technologies, including zero
13 emission locomotives.

14 There are many other regulations listed here.
15 These measures that are currently undergoing their
16 regulatory process, so they're under development right
17 now, including another thing I wanted to mention
18 specifically, our zero emission standards for space and
19 water heaters, which are listed under the other box here
20 on this slide.

21 We are also pursuing a number of off road
22 equipment measures, including setting a new standard, a
23 tier 5 standard for off road equipment as well as zero
24 emission requirements for certain manufacturers and for
25 other sources like cargo handling equipment at ports and

Audio Transcription

1 things like that that are really going to contribute to
2 reductions in the South Coast.

3 We are also continuing to pursue additional
4 measures beyond our Advanced Clean Fleets and our prior
5 Advanced Clean Trucks program for heavy duty trucks,
6 heavy duty vehicles on road with our zero emission truck
7 measure which we'll be developing over the next few
8 years.

9 Next slide.

10 So this is that same list of measures you just
11 saw, but it's showing their currently planned schedules
12 for adoption and the beginning of their implementation.
13 So the measures that have been adopted already, they're
14 shown with purple stars. And the ones that are still
15 under development, we have the planned adoption
16 schedules shown in gold stars here on this slide. And
17 then the dark blue box on each one of these lines here
18 represents the implementation begins -- well, the
19 time line for which we expect implementation to begin
20 for the program.

21 Next slide.

22 So this table shows again that suite of
23 measures, but these are the ones specifically that have
24 already been adopted and the emission reductions we have
25 quantified that are being -- contributing to the

Audio Transcription

1 attainment demonstration for this PM plan. And these --
2 I just want to mention that this does include measures
3 from this 2022 State SIP Strategy which, of course, the
4 bulk of the measures there, but there is also one or two
5 recently adopted measures from the -- that were
6 originally commitments in our 2016 State SIP Strategy a
7 few years back. That's also included in this list. And
8 so we have the NO_x, the direct PM_{2.5}, and the ammonia
9 emission reductions quantified here.

10 These reductions, you know, these programs
11 have all, as I mentioned, been adopted, but they are
12 going to provide significant emission reductions in the
13 South Coast. And they've not yet been accounted for in
14 the baseline emissions inventory, so we're quantifying
15 their emission reductions here and factoring those into
16 an adjusted baseline that is a part of the baseline in
17 the control strategy for the PM plan.

18 Next slide.

19 And this table specifically shows the suite of
20 measures that are remaining and still have yet to be
21 adopted by the CARB board as regulations and programs
22 for both the 2016 and the 2022 State SIP Strategies.
23 And then again, their corresponding NO_x, direct, PM_{2.5},
24 and ammonia emission reductions.

25 And so these are, of course, everything that

Audio Transcription

1 CARB still has on the docket that is going to support
2 attainment in 2030 of the PM2.5 Standard, in addition,
3 more, you know, really key programs as I mentioned
4 earlier. And the reductions you see at the total at the
5 bottom there, that 9.1 and the corresponding PM2.5 and
6 ammonia reductions, those represent what CARB will be
7 committing to for our emission reductions commitment to
8 support attainment in 2030.

9 Next slide.

10 So in addition to evaluating the state SIP
11 measures to support attainment, as Eric discussed, we
12 also do have to analyze our control programs, our entire
13 control programs to meet the most stringent measure, or
14 MSM control requirements for the standard. Eric touched
15 on this, but essentially, you know, this MSM is a level
16 of stringency that exceeds both the, you know, other
17 stringencies, reasonably available control measures, or
18 RACM, and best available control measures known as BACM.
19 And this is required for the plan because we're
20 requesting the five-year extension of the attainment
21 date.

22 As you may know, CARB has a unique authority
23 under the federal Clean Air Act no other state has to
24 set standards for mobile sources that are more stringent
25 than the federal government. So we've over our history,

Audio Transcription

1 you know, maximized utility of this unique authority
2 such that our mobile control programs go far beyond
3 other states and even national programs. So, you know,
4 we have been able to demonstrate this in the past and
5 EPA has approved our programs in the past as MSMS.

6 So we have, you know, updated this analysis
7 consistent with our current programs, looking at all of
8 our control measures being implemented by CARB in
9 California compared to other jurisdictions, states,
10 et cetera, talked about, also looked at our, you know,
11 measures in the State SIP Strategy. And, you know, each
12 mobile source category, as you can see here on this
13 slide, is broken into a few, you know, subcategories,
14 vehicle engine standards, in use control of the fuels.
15 And our conclusion from this analysis is that CARB's
16 programs, our current control programs for each source
17 category does meet MSM requirements. So this is just
18 kind of a summary of that here.

19 And I think that's the end of my slide deck.

20 IAN MacMILLAN: Great. Thank you very much,
21 Ariel. Appreciate all the work that CARB does with us
22 on these plans, it's always fun, and thanks for the
23 presentation there too.

24 I do see we have a couple of other questions
25 that came through from your presentation. I think that

Audio Transcription

1 they might have actually been for the prior
2 presentation.

3 So one question, I'm just going to go ahead and
4 read it here from Mary V. Asking again -- asking again
5 about San Bernardino and Muscoy data, and as they are
6 one of the first communities selected for A B 617, just
7 asking that we include that data in future
8 presentations.

9 We'll take that into account and look at that
10 for future presentations that are not the regional
11 public hearings because the slides are already out, but
12 we'll look at that for future meetings.

13 And then we have another question here as well
14 from Bobby Joe. And I'm going to ask Eric to answer
15 this briefly. I'll go ahead and just read it out.

16 With the vast expansion of new logistic centers
17 built in Ontario, Eastville, Jurupa Valley, Fontana,
18 Riverside and San Bernardino, how is AQMD and CARB
19 accounting for the fact that none of these newer
20 facilities are operating, or if they are, likely not yet
21 at full capacity?

22 Eric, you want to touch on this briefly, how we
23 accommodate and consider growth in the AQMP?

24 ERIC PRASKE: Yeah. Thanks, Ian.

25 So we rely on Southern California Association

Audio Transcription

1 of Governments growth projections from their regional
2 transportation plan sustainable community strategy. So
3 we actually received those growth factors from SCAG and
4 incorporate those into our modeling and emissions
5 projections.

6 IAN MacMILLAN: Great. Thank you.

7 And that does include a lot of new warehousing,
8 for example, in the Inland Empire as well as part of
9 their land use planning.

10 Okay. So I think we're going to go ahead and
11 move on to our next presentation. This will be our
12 third presentation, and it's going to be an overview,
13 just kind of an introductory overview of the
14 socioeconomic impact assessment that will be conducted
15 as part of the PM2.5 planning effort. So I'm going to
16 ask Tony to go ahead and give the presentation on this
17 third one.

18 TONY TIAN: Good morning, everyone. I'm Tony
19 Tian, a program supervisor in South Coast AQMD. I've
20 seen the socioeconomic impact assessment. Now let's
21 begin our -- the slide one.

22 So next slide, please.

23 So for this presentation we'll cover several
24 items. So first we'll cover cost estimates and the
25 macroeconomic impacts of this PM2.5 Plan. So

Audio Transcription

1 (inaudible) health benefit analysis.

2 So second, so for the health benefit analysis
3 we will discuss some methodologies for quantifying the
4 health benefits, specific health impacts to be
5 considered in the analysis.

6 So finally we'll present next action plans and
7 steps and staff contacts in case you have any questions.

8 So next slide, please.

9 So as we know, because of its small size, so
10 PM2.5 tends to penetrate new gases exchange regions of
11 the lung and cause many health risks, including
12 respiratory and cardiovascular diseases, asthma
13 exacerbation, and premature death.

14 So this PM2.5 Plan aims to lower PM2.5
15 emissions in South Coast Air Basin and thus achieve
16 annual PM2.5 national ambient air quality standards by
17 December 31st, 2030. And the health benefits brought
18 about by control measures in the PM2.5 Plan will be
19 quantified in the health benefits analysis.

20 So next slide, please.

21 So note that the costs, the macroeconomic
22 impacts and the health benefits control measures in
23 PM2.5 Plan has already been assessed in prior 2016 and
24 2022 AQMPs. So for this PM2.5 Plan no additional costs
25 or impacts are anticipated, and we're not prepare new

Audio Transcription

1 modified socioeconomic impact assessment. However,
2 we're due to refine the (inaudible) of the health
3 benefits of the PM2.5 reductions, and the results of
4 analysis will be presented in appendix to the PM2.5
5 Plan.

6 So next slide, please.

7 So basically we use environmental benefits
8 mapping and analysis program software developed by EPA
9 to quantify the health benefits of this PM2.5 Plan. So
10 specifically we use three input modules to do the
11 quantification.

12 So first air quality change. So staff will
13 simulate air quality change by 2030 in South Coast Air
14 Basin so (inaudible) PM2.5 to provide emission
15 reductions. So secondly, population and incidences
16 data, we obtain projections (inaudible) data from
17 (inaudible) including California Department of Finance,
18 U.S. Centers for Disease Control and Prevention, and
19 California Department Healthcare Access Commission.

20 So lastly, concentration response functions.
21 So those function is to establish quantitative links
22 between PM2.5 exposure and the various health effects.
23 So staff rely on the functions from the most reliable
24 and imputable peer-reviewed academic research to
25 quantify the health benefits of the PM2.5 reductions.

Audio Transcription

1 So next slide, please.

2 So we consider both long-term and short-term
3 effects of PM2.5 reductions.

4 So long-term benefits include premature deaths
5 avoided, decreased asthma onset and lung cancer, among
6 others. So examples of short-term benefits include
7 reduced emergency department visits, reduced hospital
8 admissions. So less (inaudible) days and workless days.

9 So next slide, please.

10 So (inaudible) health benefit assessment will
11 be released on or before May 7th, 2024, as an appendix
12 to the PM2.5 Plan. So in case you should have any
13 questions with regard to health benefits analysis of
14 this PM2.5 Plan, so we provide staff contacts in the box
15 of the slide (inaudible) appreciate it.

16 So that concludes my presentation. Thank you.

17 IAN MacMILLAN: Great. Thank you so much,
18 Tony. Appreciate that.

19 I do see a question came in in the Q and A
20 while you were speaking, but it was actually I think
21 again for the previous presentation.

22 So I'm going to go ahead and read that one out
23 and I'm going to ask Ariel if maybe she can take a quick
24 response to this question.

25 So question came in from Fabian V. If the EPA

Audio Transcription

1 does not approve the in use locomotive rule, how will it
2 affect these efforts?

3 ARIEL FIDELDY: Thanks, Ian, and thanks,
4 Fabian, for the question.

5 You know, CARB is working really closely as we
6 always do with U.S. EPA at the regional and at the, you
7 know, headquarters level to ensure that our
8 authorization waivers, all of them are going to be
9 approved, but especially, yes, for the in use locomotive
10 regulation. And we do anticipate that happening and we
11 do anticipate them approving the rule as well.

12 But by the form of our commitments, for any
13 strategy really, you know, our commitments are made at
14 the tonnage level for the total emissions reductions
15 needed. So if a specific rule, you know, doesn't go
16 forward or is not approved for some reason or another,
17 we always -- our commitment is to meet the total
18 emission reductions that we commit to in the plan. So
19 we will need to go forth and basically identify other
20 strategies, whether that is from locomotives or some
21 other source category that we can still control to
22 ensure we get those emission reductions. We would
23 essentially always be identifying other strategies, but
24 we're continuing to work really closely with U.S. EPA,
25 and we do anticipate the authorization and the rule

Audio Transcription

1 being approved.

2 IAN MacMILLAN: Great. Thanks so much, Ariel.

3 And just from the South Coast AQMD perspective,
4 I think we share the same perspective. It's really
5 critical that all three agencies take action when it
6 comes to meeting air quality standards. The local
7 government, ourselves, state government CARB, and the
8 federal government EPA, it's really critical that all
9 three do their part on emission sources within their
10 authority. So we fully support CARB's authorization
11 request on this.

12 So let's go ahead and keep moving in this
13 presentation. I think we're on to our fourth
14 presentation today, and we wanted to go over briefly the
15 California Environmental Quality Act, CEQA analysis
16 PM2.5 Plan, at least the draft, some draft results so
17 far.

18 And, Jivar, if you wanted to come on and
19 introduce yourself and cover this last topic.

20 JIVAR AFSHAR: Thank you, Ian.

21 Hello, everyone. My name is Jivar Afshar. I'm
22 an air quality specialist here at South Coast AQMD. And
23 I will be going over the CEQA portion of this
24 presentation. Thank you.

25 So CEQA is a California state law that requires

Audio Transcription

1 the state and local agencies to identify the significant
2 environmental impacts of a project and to avoid or
3 mitigate those impacts if feasible. But its main
4 purpose is to disclose to public and decision makers the
5 potential environmental effects of these projects.

6 Next slide, please.

7 So CEQA applies to PM2.5 Plan. It also applies
8 to prior air quality management plans or AQMPs. PM2.5
9 Plan contains a series of control measures, and the
10 environmental impacts of majority of these control
11 measures have been previously evaluated and certified in
12 Final Program EIRs for 2016 and 2022 AQMPs as you can
13 see in the bottom in the little figure.

14 Next slide, please.

15 To be more specific, the PM2.5 Plan contains 38
16 control measures, 9 of which are carried over from 2016
17 AQMP as you can see on the left, the orange box, and 27
18 of them from 2022 AQMP on the right, the green box.
19 This means that 36 of the control measures are retained
20 from previously adopted CEQA documents. This leaves us
21 with two new control measures in PM2.5 Plan in the
22 middle purpose box.

23 So one of these control measures focuses on
24 reducing emissions from chain-driven charbroilers, as
25 Eric mentioned at the beginning of the presentation, by

Audio Transcription

1 potentially retrofitting them with catalytic oxidizers
2 and also making future amendments to Rule 1138, which is
3 control of emissions from restaurants' operations.

4 The second new control measure in the PM2.5
5 Plan applies to emission reductions on unpaved road
6 dust. And this specific control measures only involves
7 administrative actions and will result in no physical
8 alterations.

9 I will take a deeper dive in explaining these
10 two control measures in the future slides, however, if
11 you would to take a look at a list of previously adopted
12 control measures, you can refer to Table 8.1 in Appendix
13 8 of PM2.5 Plan.

14 Next slide, please.

15 So the purpose of CEQA is to evaluate any
16 alterations made to control measures, identifying new or
17 modified environmental impacts, and also determine
18 whether a new CEQA document needs to be prepared or not.

19 Next slide, please.

20 So this is the first new control measure out of
21 the two that I am going to talk about. This specific
22 control measure focuses on further reducing emissions
23 from commercial cooking. And it expands upon previous
24 control measure that was outlined in 2016 AQMP.

25 Back in 2016 the AQMP focused and targeted

Audio Transcription

1 under-fired charbroilers and offered multiple control
2 options. However, in PM2.5 Plan we shift our focus to
3 emission reductions from chain-driven charbroilers
4 equipped with catalytic oxidizers.

5 It's noteworthy to mention that this
6 enhancement in utilization on catalytic oxidizers offer
7 easy installation with minimal maintenance requirements.
8 And as a component of a new measure, these catalytic
9 oxidizers were previously assessed in final subsequent
10 assessment for Rule 1138.

11 So these changes will result in improving
12 operational air quality impacts by greater reductions in
13 PM2.5 emissions. And the overall impacts are expected
14 to either mirror or be less severe than those previously
15 analyzed for under-fired charbroilers in our previous
16 CEQA documents.

17 Next slide, please.

18 This is the second control measure that I
19 talked about earlier, which is emission reductions from
20 unpaved road dust, which proposes to create an inventory
21 of unpaved roads and parking lots within the
22 jurisdiction of South Coast AQMD. And as I mentioned
23 previously, it's an administrative exercise, therefore,
24 it has no environmental impacts.

25 Next slide, please.

Audio Transcription

1 Apart from the 2000 new control measures
2 discussed earlier, the remaining control measures align
3 with those adopted in 2016 and 2022 AQMP and are not
4 expected to yield in additional changes in operational
5 air quality benefits or environmental impacts. And
6 because of that, the analysis of PM2.5 Plan does not
7 change the conclusions from our previous CEQA documents.

8 Next slide, please.

9 So to conclude, the control measures in PM2.5
10 Plan, new and previously analyzed, reduce PM2.5
11 emissions and result in no additional environmental
12 impacts. And since the PM2.5 Plan does not present
13 substantial new information in comparison to what was
14 analyzed in our previously adopted CEQA documents and
15 the effects of PM2.5 Plan have sufficiently been
16 outlined in previous CEQA documents, this plan qualifies
17 as a later activity within the scope of previously
18 approved CEQA documents under CEQA guidelines Section
19 15168(c).

20 If you are interested, you can access the
21 detailed CEQA analysis in Appendix 8 of the PM2.5 Plan.

22 This concludes my presentation. And I will
23 hand it over to Ian.

24 IAN MacMILLAN: Great. Thank you very much,
25 Jivar, I really appreciate the work on the CEQA and then

Audio Transcription

1 the presentation here.

2 I don't see any questions in the Q and A box
3 right now. I think we've gotten everything that's been
4 typed in so far. I think we're at the part of the
5 agenda now where we'd like to open it up for any public
6 comment, remaining questions. And this would be on any
7 of the four presentations, whether it's the AQMP itself,
8 CARB's measures, the socioeconomic impact assessment, or
9 the CEQA analysis.

10 If anybody has any questions, again, you can
11 raise your hand at the bottom of the screen, click that
12 little button. If you're on the phone, press star 9.
13 And we can just take any general comment or any
14 questions if you'd like. And I'll pause right here in
15 case anyone wants to click that.

16 All right. Not seeing any, we are looking to
17 bring this to our board in June for their consideration.
18 We do have three more regional public hearings that
19 we're going to be holding this week and next week as
20 well to go over the same material, but really, you know,
21 trying to focus on each individual county, but, you
22 know, anybody is free to attend any of those regional
23 public hearings, provide some feedback there.

24 If you also have any feedback you'd like to
25 provide or any questions, feel free to reach out to

Audio Transcription

1 staff directly, and we're more than happy to engage with
2 whatever stakeholders on this.

3 So I'm going to give one last call. Any more
4 questions or comments?

5 Not seeing any. So I'll give you a thank you
6 to all the stakeholders for joining us today, really do
7 appreciate it. Thank you to all the staff who
8 participated and prepared materials for today. And I
9 think with that we're going to conclude this meeting
10 today and we'll pick it up at the next hearing tomorrow.

11 All right. Thank you very much, everybody.
12 Have a great day.

13 (End of recording.)

Summary of Public Comment Received at the PM2.5 Plan Regional Public Hearing for Riverside County April 24, 2024

The audio recording from this meeting was unsuitable for transcription. As such, a summary of public comment is provided below in lieu of the transcript.

Stacey Ramos, CCAEJ

Comment: Large growth in warehouses has resulted in an increase in truck trips to the Inland Empire. How does the air quality modeling account for this growth?

Response: Growth factors, including those for the logistics industry, are provided by the Southern California Association of Governments and these factors are used to project emissions in the future.

Oskar Zambrano

Comment: City councils approve development projects (resulting in businesses such as warehouses and marijuana facilities) which seem to bypass the CEQA process. Where can I find more information on a specific CEQA assessment?

Response: Land use decisions for development projects are subject to CEQA and are made by the local planning authority/government agency overseeing the approvals of these projects. To find out what CEQA determination was made for a specific project, please contact the local planning authority/government agency. In addition, the State Clearinghouse of the Governor's Office of Planning and Research at maintains a database of CEQA documents for a wide variety of projects throughout California which is accessible from the following website at: <https://ceqanet.opr.ca.gov>.

Comment: Which agency has land use authority?

Response: While the South Coast AQMD does not have land use authority, most local city and county planning departments are land use agencies with authority over development projects and land use decisions.

Comment: Which agency is responsible for enforcing mitigation measures such as limiting truck idling?

Response: A CEQA document associated with a land use development project may have adopted mitigation measures which are enforced through a Mitigation, Monitoring and Reporting Plan that will specify which government agency is responsible for enforcing the various mitigation measures. Truck idling is jointly enforced by CARB and South Coast AQMD.

Comment: Can truck traffic be curtailed?

Response: Most local city and county planning departments operate pursuant to a General Plan which contains a transportation element that sets the policy foundation for traffic, transportation and goods movement. In addition, while the South Coast AQMD does not have authority to limit truck traffic, warehouses that attract truck traffic are subject to South Coast AQMD's Rule 2305 – Warehouse Indirect Source Rule. Specifically, Rule 2305 requires owners and operators of applicable warehouses to take actions to reduce emissions or exposure to air pollution.

Comment: What is the timeframe for short-term and long-term health effects of PM2.5?

Response: Short-term health effects occur over a 24-hour period, while long-term effects are experienced over a year or more.

SOUTH COAST AQMD
REGIONAL PUBLIC HEARING FOR
SOUTH COAST AIR BASIN ATTAINMENT PLAN
FOR THE 2012 ANNUAL PM2.5 STANDARD

APRIL 25, 2024

REQUESTED PORTIONS:

34:25 - 36:26

50:00 - 51:03

Transcribed by:
Diana Sasseen
CSR No. 13456
Job No. 10141371

Audio Transcription

1 (Begin 34:25 - 36:26.)

2 IAN MacMILLAN: I want to open it up again in
3 case there's any questions or comments on this agenda
4 item, on CARB's measures. Feel free to raise your hand.

5 I do see we have one hand raised. Laura
6 Hayter, do you have a question or comment?

7 LAURA HAYTER: Yes. Does the oil industry
8 have to have the most strict standards also? And what's
9 being done -- what are the emissions from the various
10 stationary oil facilities and pipelines?

11 IAN MacMILLAN: So I can maybe take the first
12 crack at this, and I'll see if any of my staff also
13 wants to weigh in.

14 So all controls or all sources need to have
15 Most Stringent Measures in place. It doesn't mean that
16 we aren't going to continue to regulate and continue to
17 find new reductions but we do need to demonstrate Most
18 Stringent Measures across all categories I believe.

19 And I see Eric has popped on. I'm not sure
20 if -- any clarification needed here?

21 ERIC PRASKE: I think you covered it well, Ian.

22 Yeah, Most Stringent Measures does not exempt
23 any category. We have to look at everything under our
24 authority.

25 IAN MacMILLAN: Great. And then you also have

Audio Transcription

1 a question about the level of emissions in that sector.

2 We do have in the PM2.5 Plan itself we have a
3 lot more information about emission inventory for all of
4 the different sectors of emissions. So feel free to go
5 ahead and look in there. And if you have questions, feel
6 free to reach out, and we can help maybe point you to
7 where you can find more specific information, but we
8 have a lot of detailed information in that plan itself.

9 Did that answer your question, Laura?

10 LAURA HAYTER: Thanks. Yeah.

11 IAM MacMILLAN: Great. Thank you for that
12 question.

13 (End of requested portion.)

14 (Begin 50:00 to 51:03.)

15 IAM MacMILLAN: I do see actually one hand just
16 came up. Laura Hayter.

17 LAURA HAYTER: The carbon dioxide pipeline, has
18 there been a leak, and did that affect the emissions
19 that much? What effect did it have in the total carbon
20 emissions?

21 IAM MacMILLAN: I'm not quite sure of the
22 question you're asking, but it sounds like you're asking
23 about a specific incident.

24 It might be better to take some of these
25 questions off line and we can make sure that we can try

Audio Transcription

1 to direct you to the right resources for information
2 you're looking for.

3 We had contact information here in the
4 presentation. I would -- maybe let's start with either
5 Eric or Sing-Mi. Their contact information is in the
6 slides, and maybe reach out to them. We an try to
7 direct you to the right resources. Does that okay?

8 IAN MacMILLAN: Great. Super.

9 (End of requested portion.)

SOUTH COAST AQMD
REGIONAL PUBLIC HEARING FOR
SOUTH COAST AIR BASIN ATTAINMENT PLAN
FOR THE 2012 ANNUAL PM2.5 STANDARD

MAY 1, 2024

REQUESTED PORTIONS:

4:12 - 4:21

12:50 - 15:57

22:37 - 27:57

31:12 - 34:35

37:53 - 38:23

40:09 - 53:20

Diana Sasseen
CSR No. 13456
Job No. 10141761

Audio Transcription

1 (Begin 4:12-4:21).

2 UNIDENTIFIED SPEAKER: Was that a voluntary
3 designation or --

4 ERIC PRASKE: We requested a reclassification
5 to serious.

6 UNIDENTIFIED SPEAKER: Okay. Got it. Okay.

7 (Begin 12:50-15:57)

8 UNIDENTIFIED SPEAKER: So I'm curious how this
9 plan --

10 UNIDENTIFIED SPEAKER: Can you be sure to speak
11 to the microphone, because we are required to record
12 this.

13 UNIDENTIFIED SPEAKER: Gotcha.

14 UNIDENTIFIED SPEAKER: Thank you.

15 UNIDENTIFIED SPEAKER: So I'm curious as far as
16 how this plan relates to the kind of brewing EPA action
17 to basically reject the South Coast -- I think it was
18 the PM plan. So I was wondering if you could go -- or
19 basically I know that US EPA is looking at possibly
20 rejecting a South Coast plan. Could you maybe talk
21 about how this plan interacts with that?

22 ERIC PRASKE: So I think you're referring to
23 the 1997 ozone standard --

24 UNIDENTIFIED SPEAKER: Okay. Gotcha.

25 ERIC PRASKE: -- contingency measure plan,

Audio Transcription

1 right, that was submitted in 2019?

2 UNIDENTIFIED SPEAKER: Yeah. Okay. Yeah, I
3 just wanted to make sure.

4 ERIC PRASKE: Yeah. So this is a different
5 standard, it's for PM2.5 Standard, so it's on a
6 completely separate track from that plan.

7 UNIDENTIFIED SPEAKER: Okay. Gotcha.

8 UNIDENTIFIED SPEAKER: On the monitoring data
9 here which is from 2018 you mentioned?

10 ERIC PRASKE: Yep. The monitoring data is
11 measured PM2.5 level in 2018, yes.

12 UNIDENTIFIED SPEAKER: 2016 through 2019
13 average.

14 UNIDENTIFIED SPEAKER: Okay. So it was
15 averaged through multiple, okay, so it wasn't just one
16 specific year.

17 UNIDENTIFIED SPEAKER: No, it was more year
18 average.

19 UNIDENTIFIED SPEAKER: Okay. Okay. And these
20 current stations as far as we know.

21 ERIC PRASKE: Yeah.

22 UNIDENTIFIED SPEAKER: Yeah, we still continue
23 to monitor at all of the stations, it's just I think we
24 were (inaudible) again, you have a base here that you
25 build off of on the plan (inaudible) monitoring data

Audio Transcription

1 (inaudible), but we continue to collect monitoring
2 data.

3 UNIDENTIFIED SPEAKER: Okay. Very good.

4 UNIDENTIFIED SPEAKER: I know on that section
5 that (inaudible) was just pointing out, that there is an
6 exemption for exceptional events which, you know,
7 obviously we know wildfires, 4th of July, things like
8 that. Do we have a detailing of how many exceptional
9 events there are in a particular year?

10 ERIC PRASKE: So -- go ahead.

11 UNIDENTIFIED SPEAKER: So it varies every year,
12 but then usually we flag the 4th of July, fireworks, and
13 then the New Year fireworks. And there are a few days,
14 maybe wildfire effects here and there, but then when it
15 comes to annual standards, it's limited numbers. But it
16 changes year to year.

17 UNIDENTIFIED SPEAKER: What's the limit?

18 UNIDENTIFIED SPEAKER: Limited numbers. Not
19 many days going into it.

20 UNIDENTIFIED SPEAKER: Okay.

21 UNIDENTIFIED SPEAKER: We can check how many
22 days actually reflected, but it's very few.

23 UNIDENTIFIED SPEAKER: Okay.

24 UNIDENTIFIED SPEAKER: These two events are
25 always.

Audio Transcription

1 UNIDENTIFIED SPEAKER: Yeah, 4th of July and
2 New Years is kind of well known, so sometimes the
3 fireworks show in the neighborhood is better than the
4 professional ones, so --

5 UNIDENTIFIED SPEAKER: That's right. You can
6 smell it too.

7 UNIDENTIFIED SPEAKER: Monitoring was difficult
8 during the 4th of July for (inaudible), I'll tell you
9 that.

10 UNIDENTIFIED SPEAKER: Those heavy metals.
11 It's nasty.

12 UNIDENTIFIED SPEAKER: I tell you those labs
13 came back; what's going on? Oh, fireworks. Yeah.
14 Thank you.

15 (Begin 22:37-27:57)

16 UNIDENTIFIED SPEAKER: CARB.

17 SYLVIA: Yes.

18 UNIDENTIFIED SPEAKER: In state level, I mean
19 we're looking at other air districts, so CARB's umbrella
20 covers all the air districts.

21 SYLVIA: Right. Right.

22 UNIDENTIFIED SPEAKER: So looking at other best
23 practices with them, is that incorporated in what
24 they've -- in their attainments, or are they all -- from
25 the CARB perspective, (inaudible) air district.

Audio Transcription

1 SYLVIA: Well, when we're looking at -- so I
2 mean, you know, AQMD did identify -- they looked at
3 other districts, but for mobile sources, I mean CARB is
4 the only one in the state that can regulate mobile
5 sources. And so we -- but we did look at other states.
6 We looked at other states that had different idling
7 requirements or different -- other types of measures and
8 things like that. And, you know, we did come to the
9 conclusion that we did, you know, meet these
10 requirements. You know, other states do have the
11 opportunity to, you know, adopt our regulations.

12 UNIDENTIFIED SPEAKER: But I think you also
13 with all of your measures that you report here --

14 SYLVIA: Yeah.

15 UNIDENTIFIED SPEAKER: -- you're looking at how
16 would that affect South Coast specifically --

17 SYLVIA: Yeah, I mean --

18 UNIDENTIFIED SPEAKER: -- and when you analyze
19 San Joaquin and you (inaudible) for them.

20 SYLVIA: I mean we would --

21 UNIDENTIFIED SPEAKER: Same regulation, but it
22 affects them differently, right?

23 SYLVIA: Well, I mean they have different
24 sources. And so when you're doing something like Most
25 Stringent Measure, like we're looking at what the

Audio Transcription

1 sources are in the South Coast, and we had some
2 difference -- like probably the biggest difference
3 between the two, you know, because San Joaquin is also
4 doing something right now, was for South Coast we looked
5 at OGV, you know, that's a big source, that's not a
6 source in San Joaquin for San Joaquin, we looked at
7 (inaudible) tractors. That's not really a big source
8 (inaudible).

9 UNIDENTIFIED SPEAKER: Okay.

10 UNIDENTIFIED SPEAKER: So looking at other
11 states though, if they're -- other states that don't
12 have, say, the -- I would say -- here our state
13 reference in controlling the measures in comparison --

14 SYLVIA: Right.

15 UNIDENTIFIED SPEAKER: -- what was looked at
16 there and seeing? Are we -- leaps and bounds we're
17 ahead of them since more of other states will have -- or
18 have struggled to implement versus where we're at, and
19 seen in comparison to where we are at now, are we above
20 that level? Right? That may be zero to no regulation
21 to say as an example to where we are now and how we
22 progress from there?

23 SYLVIA: I mean I will say that we did find
24 someone that had a more stringent idling requirement;
25 however, you know, CARB with the truck and bus rule

Audio Transcription

1 requires 2010 engines, so their idling requirement did
2 not -- was due to a different type of engine. And so
3 our engines were already cleaner. And so there was
4 just, you know, a handful of things.

5 I believe there was someone that required all
6 school busses to be electric. You know, and when we're
7 doing this, we're looking at this from the state
8 perspective; we are pushing, you know, where we can, and
9 everywhere to go electric. But overall when you're
10 looking at like, you know, all the requirements that we
11 have in general, we have the most stringent measures.

12 And it kind of goes to say, you know, with the
13 air quality problems that we have here in California
14 compared to the rest of the state; I mean, like even in
15 this 12 microgram standard there's only three areas that
16 don't meet it in the United States, and they're all in
17 California.

18 UNIDENTIFIED SPEAKER: One question I had was
19 regarding the measure schedule. So on the regulations
20 passed before 2024 --

21 SYLVIA: Right.

22 UNIDENTIFIED SPEAKER: -- the ones that have
23 already passed, the implementation date was -- of those
24 regulations were scheduled within a year or two from
25 passage of the ultimate regulation. But when you start

Audio Transcription

1 going down further into like 2025 and beyond, there
2 seems to be like a three- to four-, sometimes five-year
3 gap between the passage date and the implementation
4 deadline. Is that a facet more about kind of the
5 (inaudible) sort of nature of the regulation or is that
6 because those regulations are tougher nuts to crack or
7 will require more -- you know, longer time to implement?

8 SYLVIA: Yeah, I think it's, you know, it's a
9 matter of goals. You know, the Tier 5, that's a new
10 emission standard.

11 UNIDENTIFIED SPEAKER: Right.

12 SYLVIA: You know, manufacturers need time to
13 develop that. You know, that's I think something that,
14 you know, normally would have a lead time on that
15 process. The zero emission space and water heater,
16 again, it's pushing the boundaries, you know, on a
17 statewide basis.

18 But this is -- and part of these on these when
19 can it be implemented, and when we're talk in our
20 regulatory divisions, this is the information that they,
21 you know, have given us. And then the emission
22 reductions that are included in the plan are based on
23 that.

24 UNIDENTIFIED SPEAKER: Got it. So the rail
25 implementation, so we just start -- so what is -- what's

Audio Transcription

1 the phase-in for them at the moment, because I know
2 rails is kind of a touchy one.

3 SYLVIA: Right. I'd have to -- you know, I'm
4 not really the expert on that. It's my understanding,
5 you know, the spending account, I'd have to look to see
6 when that actual date start is.

7 UNIDENTIFIED SPEAKER: Okay.

8 UNIDENTIFIED SPEAKER: I think right now that's
9 still pending also at EPA for their consideration on
10 authorizing that rule too. That's another process
11 that's underway.

12 SYLVIA: Right. And they have had their public
13 hearing on that.

14 UNIDENTIFIED SPEAKER: Right.

15 (Begin 31:12-34:35)

16 UNIDENTIFIED SPEAKER: The data that was used
17 to do the calculation, what reference, when were the --
18 what's the age of the data (inaudible) the modeling?

19 UNIDENTIFIED SPEAKER: Which type of data I
20 guess?

21 UNIDENTIFIED SPEAKER: The health risks.

22 UNIDENTIFIED SPEAKER: Health risk data, it's
23 sort of a spread. So it's mostly -- I guess everything
24 is in a forecasted year, so when we look at 2030, we're
25 looking at what the forecast and like death rate is in

Audio Transcription

1 2030. That's from the California Department of Finance.

2 I think most of this we use the same data that
3 was collected in the 2022 AQMP, just since it's not that
4 much different or not that much updated and sort of a
5 large data-gathering effort to get fully updated on all
6 those things.

7 That being said, I believe everything from the
8 2022 AQMP was in the 2020 age range for data recency.
9 Some of those end points as far as like incidence rates
10 that aren't easily publicly available are taken from
11 like academic research that is basically just as most as
12 recent as we could find. I don't have specific numbers
13 off the top of my head for all of it, but I'm sure we
14 could dig all that up.

15 There's also a pretty detailed discussion in
16 the technical appendix or the technical discussion
17 portion of the report that will be up on May 7th. So
18 you can refer there, or definitely reach out and we can
19 answer specific questions that come up.

20 UNIDENTIFIED SPEAKER: I think that general,
21 it's we get as recent as we can --

22 UNIDENTIFIED SPEAKER: Yeah.

23 UNIDENTIFIED SPEAKER: -- that's, you know --
24 got to find the right adjective here. I was going to
25 say "validated," but it's, you know, peer-reviewed, you

Audio Transcription

1 know, kind of scrutinized and it's appropriate for use.
2 But we get as recent data as is available.

3 UNIDENTIFIED SPEAKER: So they used independent
4 like academic research, and also other agencies,
5 specifically OEHHA, Office of Environmental, I know they
6 collect a lot of data; is that being referenced or is
7 that being used? I know that they collect some like
8 detailed information --

9 UNIDENTIFIED SPEAKER: Right, I'm not sure --

10 UNIDENTIFIED SPEAKER: -- to get a little more
11 specific of the impact.

12 UNIDENTIFIED SPEAKER: I'm not sure we use
13 anything from OEHHA, but as far as academic research is
14 concerned for those like concentration response
15 functions, those are all specific to the L.A. region,
16 more California specific as we can get, it's all
17 peer-reviewed research, and all been sort of
18 collaborated on as far as what sort of end points we can
19 look at as far as the quality of the research that we're
20 pretty confident that there's a causal relationship
21 between the PM2.5 concentrations and health impacts, and
22 that's also something that we collaborated with an
23 external consultant on, Industrial Economics, which does
24 a lot of this type of health benefit work for a number
25 of agencies.

Audio Transcription

1 So yeah, OEHHA, I don't know if we use any data
2 from OEHHA in this health benefit analysis. Is there a
3 specific type of --

4 UNIDENTIFIED SPEAKER: We use them a lot in a
5 lot of our other processes, (inaudible) paramount with
6 all the Hexachrome and all that there. We rely very
7 heavily on what OEHHA does for the toxics assessments.
8 So it sort of depends on the purpose of the health
9 study, who develops the guidance and the, you know, the
10 technical supporting information.

11 UNIDENTIFIED SPEAKER: Thank you.

12 UNIDENTIFIED SPEAKER: No questions on my end.

13 UNIDENTIFIED SPEAKER: Great. Thank you.

14 (Begin 37:53-38:23)

15 UNIDENTIFIED SPEAKER: Could you maybe explain
16 what an administrative exercise is?

17 UNIDENTIFIED SPEAKER: So administrative
18 exercise is like creating an inventory. Basically
19 there's no physical change.

20 UNIDENTIFIED SPEAKER: Okay.

21 UNIDENTIFIED SPEAKER: We are not -- it's
22 just -- we're just gathering data at the moment. It's
23 not requiring like any equipment to install anything,
24 any -- so there's no physical change, so it's an
25 administrative exercise. It's not going to affect the

Audio Transcription

1 environment in any way.

2 (Begin 40:09-53:20)

3 UNIDENTIFIED SPEAKER: Any questions you might
4 have, now is a good time.

5 UNIDENTIFIED SPEAKER: So one thing I am
6 curious about, especially with the -- you know, with
7 South Coast AQMD currently considering the ports and
8 railyard ISR, how -- basically what would this -- what
9 would those rules mean for this particular plan?

10 UNIDENTIFIED SPEAKER: Maybe I'll take that
11 one.

12 So on the indirect source rules, they certainly
13 would help. I think as we're going through both those
14 rule makings, we're still -- rail is a little farther
15 along than ports --

16 UNIDENTIFIED SPEAKER: Right.

17 UNIDENTIFIED SPEAKER: -- but we're still
18 working through what exactly would those do; and
19 especially for the time line for this plan, for 2030, I
20 think both of those rules are looking at, you know,
21 potential implementation that would cross over through
22 2030 right before and after, so I don't think we have
23 specific numbers yet. I don't think we have anything in
24 this plan right now that is quantifying what the
25 benefits are.

Audio Transcription

1 But we do have those measures included in the
2 plan, same as the 2016 AQMP, the 2022 AQMP, and now for
3 this plan that are there, we're working on it; but the
4 specific numbers we're going to hold off on any
5 quantifying commitment on those and kind of push that
6 more to rule making. And in some ways for SIP purposes,
7 which is what this exercise really is, that often can
8 even come after rule making as well.

9 UNIDENTIFIED SPEAKER: Understood. Certainly
10 would restate our support for a strong rules in either
11 case, try to get those passed as expediently as
12 possible, but appreciate that response.

13 UNIDENTIFIED SPEAKER: (Inaudible) rules given
14 to the more detailed ground level community base as far
15 as seeing the impact. It's what the inspecting and also
16 enforcement, how do we know it's affecting -- I mean
17 we're going through this whole process, how are we
18 seeing, you know, some of these time lines we start
19 getting into 2025, 2026 forward. Maybe I'm getting too
20 deep into the weeds.

21 How are we going to start seeing the actual
22 effect of it, what are we -- is that cascading down into
23 more of the ground level? Are we going to be
24 inspecting, are we going to be doing inventory checks on
25 some of these different sources to see that we're

Audio Transcription

1 starting to see some of this going along to be
2 implemented? Maybe I'm --

3 UNIDENTIFIED SPEAKER: Maybe I can take a first
4 crack from the AQMD side of it, and then, Sylvia, I
5 don't know if you want to talk from the CARB side. We
6 don't have our enforcement folks here, so, you know, I
7 want to be careful about what I say for them because I
8 can feel a virtual kick anything I talk about
9 enforcement.

10 But yes we enforce our rules, of course, right.
11 And then can we have a inspector at every facility at
12 all times? No, right? Resources don't allow that.

13 There are, you know, a variety of mechanisms
14 that are in different rules, including a lot of these
15 control measures. One of the things that we do when we
16 craft our rules is we try to think about how do you
17 enforce it. So you imagine something like home heating.
18 Are we really thinking of enforcing on individual
19 homeowners? Boy, that is really -- there's a lot of
20 challenges there as opposed to is it a manufacturer's
21 mandate or distributor's mandate? Right? And so it
22 gets to enforceability. How do you enforce a provision?

23 A lot of that still is worked out in every
24 individual rule, but there are some, you know, things
25 that are being done. For example, you mentioned

Audio Transcription

1 inventory, emissions inventory. So if you look at AQMD,
2 we have an emissions reporting program that every year
3 large facilities need to report, CARB recently did a
4 rule. Criteria talks (inaudible) reporting regulation
5 that really expands the number of facilities that report
6 emissions every year. So a lot more granular data is
7 coming in from a lot more facilities, thousands and
8 thousands more, and that's being phased in. But that
9 gives us a lot more information about, oh, there's a
10 little spike in emissions that really helps our -- I
11 know, I've talked to plenty of inspectors, they look at
12 this data before they go on inspections, and it helps
13 inform them what to look for. So there's different ways
14 to try to get at it.

15 The last thing I'm going to say, because any
16 time enforcement comes up is if you see something, if
17 something smells funny and you aren't sure about it,
18 1800GotSmog, right? That really helps our inspectors.

19 So I don't know, Sylvia, if you want to add
20 anything from the CARB perspective on that.

21 SYLVIA: Yeah, I mean enforcement is something
22 that's critical for all of these rules, and so each of
23 the rules that CARB's, you know, adopting has, you know,
24 an enforcement element to it.

25 And, you know, we learn also from our rules. I

Audio Transcription

1 don't know if you remember, you know, the truck and bus
2 regulation, you know, we were out in the field looking
3 around and we realized that people were somehow getting
4 around the requirement for, you know, having a 2010
5 truck. And so then we worked with our legislatures and
6 stuff and so then we got a registration hold.

7 And so now, you know, we -- you know, when
8 you're developing these rules, you come up with
9 enforcement mechanisms, and sometimes you have to
10 reassess them and see if they're working, but
11 ultimately, you know, I mean when you look at emissions,
12 they are going down, you know, especially NOx emissions.
13 If you would get, you know, ambient NOx monitors, those
14 trends are on a downward.

15 And, you know, air quality, you know, we've had
16 some hiccups lately, but they are -- it is improving. I
17 mean last year was -- for across the state was a great
18 year for PM, it was one of the first years we had that
19 we didn't have a lot of wildfires over the summer, and
20 so you could actually see, you know, what air quality
21 should be when it's not -- when we don't have these
22 extensive wildfires.

23 UNIDENTIFIED SPEAKER: One other question I had
24 was relating to -- so when we look at the air quality
25 standards, you know, those are primarily looking at

Audio Transcription

1 averages at different monitoring sites at the basin,
2 it's kind of a district-wide average. What are some of
3 the things that can be done to make sure that the
4 communities with the highest levels are the ones
5 experiencing the benefits? I know in this case it might
6 be a little bit more limited since we are talking about
7 just a handful of, what, two new rules and two amended
8 rules, but just making sure that the communities that do
9 have higher levels of particulate matter counts, worse
10 air pollution are benefiting the most from these
11 proposals.

12 SYLVIA: I mean, I can just say from the CARB
13 side, when you look at what the sources we're targeting;
14 I mean we are really targeting sources that are near
15 disadvantaged communities, you know, trains, trucks, you
16 know, port sources. And so, you know, I think we are,
17 you know, listening to communities and trying to, you
18 know, target our controls there. And so, you know, you
19 can do, you know, some analysis and, you know, I don't
20 know if -- you guys have done some in the past.

21 UNIDENTIFIED SPEAKER: Yeah, we have.

22 So I think sort of two thoughts in addition to
23 what Sylvia just said.

24 So in our 2022 AQMP, that socioeconomic impact
25 assessment we did do an environmental justice analysis

Audio Transcription

1 looking at the geographic distribution of where the air
2 quality benefits are and, you know, mapping that
3 against, you know, where all the different communities
4 are, and found that overall all these strategies have a
5 net benefit for environmental justice communities in our
6 region. And so that's really important, right? That's
7 exactly to your point.

8 The other is I want to make sure it's clear; so
9 when we're showing the monitors, and there's averaging
10 that's done to compare against the standard, but not
11 across different monitors. You don't average
12 San Bernardino with Upland with Long Beach, right? You
13 look at each individual monitor and you average across
14 years at the same site, right? So you have to have
15 every community where there's monitoring, right, has to
16 meet that standard, right? So that's how we make sure
17 that every community sort of meets a minimum level of
18 air quality.

19 UNIDENTIFIED SPEAKER: Okay. Great.

20 UNIDENTIFIED SPEAKER: Maybe one final point.
21 Maybe it's getting into the weeds a little too much.
22 But we also look at areas that don't have a monitor too.
23 And we have to make sure that they are also in
24 attainment. So not every environmental justice
25 community has a PM2.5 monitor --

Audio Transcription

1 UNIDENTIFIED SPEAKER: Right.

2 UNIDENTIFIED SPEAKER: -- but our analysis
3 assures that they will be in attainment.

4 UNIDENTIFIED SPEAKER: How do you do that
5 modeling for communities that don't have a monitor?

6 SYLVIA: (Inaudible) is an unmonitored area
7 (inaudible) --

8 UNIDENTIFIED SPEAKER: Computer modeling. Very
9 detailed computer modeling.

10 SYLVIA: Mark.

11 UNIDENTIFIED SPEAKER: You have to come on
12 over.

13 UNIDENTIFIED SPEAKER: Yeah, maybe come over
14 here so you can be picked up.

15 UNIDENTIFIED SPEAKER: So we use these air
16 quality models (inaudible). We use these air quality
17 models that model the entire region. I mean, you can
18 think of these air quality models as when you look at
19 the weather forecast, there are no weather station
20 everywhere, right, but you have the model (inaudible),
21 okay, this is the weather (inaudible). So air quality
22 model is the same.

23 And so yeah, we don't have measurements
24 everywhere, but we have these models. And then so we
25 use these measurements where we have them to compare

Audio Transcription

1 them with the modeling, we see that the model does a
2 reasonably good job, so then we have some confidence
3 that the modeling is telling us -- it's telling us
4 whatever it is telling us in the regions that we don't
5 have measurements, we can also trust models to tell us
6 what the (inaudible) of air quality is in there.

7 UNIDENTIFIED SPEAKER: Got it. Understood.

8 UNIDENTIFIED SPEAKER: In the monitoring,
9 does -- is there engagement between, say, does CARB have
10 capacity or even EPA and have these -- we'll say if
11 there's regions where maybe we're monitoring here, are
12 there -- where maybe CARB is monitoring somewhere else,
13 and then we have building that up --

14 SYLVIA: Right.

15 UNIDENTIFIED SPEAKER: -- is that somewhere
16 over here because I -- I vaguely remember in 2016 that
17 we started having that conversation about
18 cross-referencing data and using equipment and all that.

19 SYLVIA: Yeah. There is a requirement that
20 every year by July 1st of the year that you submit an
21 annual network plan to EPA, and that annual network plan
22 actually has to go through a public review process where
23 you talk about, you know, changes to the network and
24 things like that. But also a new element of it is
25 addressing environmental justice communities. That's

Audio Transcription

1 part of the new thing.

2 And then every five years, and I think it's
3 next year, you actually have to do a network assessment
4 where you are -- are you meeting the monitoring
5 objectives, because EPA has some very strict like
6 monitoring objectives about what has to be monitored,
7 how -- what is a monitor, is it a high site. You know,
8 it's looking at MSAs and those kind of things. But, you
9 know, every five years then you do a reassessment on
10 that. And so that's happening next year.

11 And both of these documents are -- will be out
12 for public comment so people can comment on those. You
13 know, South Coast will be doing theirs shortly. And
14 CARB does one for the smaller districts and areas of the
15 state that don't have their own monitoring organization.

16 UNIDENTIFIED SPEAKER: And I think there's also
17 a difference sometimes in the toxics monitoring, that
18 you do get multiple agencies in some cases pulling
19 resources there for versus there's criteria pollutant
20 monitoring, I mean, you know, we actually get some
21 funding from -- from EPA, but largely it's up to the
22 district to deploy all those monitors, but we certainly
23 coordinate with, you know, the three agencies.

24 SYLVIA: Yeah, and there's, you know, quality
25 control requirements, there's a lot to it that is -- you

Audio Transcription

1 know, because you want make sure that the monitors are,
2 you know, accurate.

3 UNIDENTIFIED SPEAKER: And what you see in L.A.
4 is comparable to what you see in New York to what you
5 see in Florida, to what you see everywhere.

6 SYLVIA: Yeah, so that --

7 UNIDENTIFIED SPEAKER: Right, level the playing
8 field.

9 UNIDENTIFIED SPEAKER: And actually, as we get
10 into this, I mean that's how we're going to -- the
11 easiest to understand, if we go back to our communities,
12 if we start seeing the monitoring data, right, is what's
13 going to start checking all this work, that it's okay,
14 we're starting to see, as we've already seen, as you
15 mentioned, progress.

16 SYLVIA: Yeah. No, it's -- I mean monitoring
17 data is super important to look at. And looking at it
18 every day is very helpful. Then you can see changes and
19 you know when, you know, air quality is, you know, bad
20 or, you know, you shouldn't be outside and stuff. And
21 so I think it's important, you know, I think -- and
22 nowadays there's so much available air quality data out
23 there that you can look, you know, instantaneously, oh,
24 should I go outside or not. And so --

25 UNIDENTIFIED SPEAKER: You know, there are some

Audio Transcription

1 agencies who have an app. I hear South Coast AQMD has a
2 nice app with air quality alerts on there. Just saying.
3 It's award winning.

4 SYLVIA: Sorry about that.

5 UNIDENTIFIED SPEAKER: Yeah, it's good. It's a
6 good app, I use it quite a bit.

7 UNIDENTIFIED SPEAKER: There we go. Speak that
8 into the mic.

9 UNIDENTIFIED SPEAKER: I highly recommend
10 downloaded (inaudible) app.

11 UNIDENTIFIED SPEAKER: Thank you. That's good.

12 UNIDENTIFIED SPEAKER: So any other questions,
13 comments on any of this?

14 No? Well --

15 UNIDENTIFIED SPEAKER: Not on the record.

16 UNIDENTIFIED SPEAKER: Thank you very much.

17 UNIDENTIFIED SPEAKER: Thank you all for
18 coming, do appreciate it. All of our contact
19 information is in there, feel free to reach out any
20 time. So thanks a lot for coming out, and I think with
21 that we'll officially adjourn, but we'll be here to keep
22 talking.

23 (End of recording.)

REPORTER'S CERTIFICATE

I, the undersigned, a Certified Shorthand
Reporter of the State of California, do hereby certify:

That the foregoing electronically-recorded
proceedings were transcribed by me to the best of my
ability.

I further certify I am neither financially
interested in the action nor a relative or employee of
any attorney or party to this action.

IN WITNESS WHEREOF, I have this date
subscribed my name.

Dated: 05/13/2024

South Coast Air Basin Attainment Plan for the 2012 Annual PM2.5 Standard

Board Meeting
June 7, 2024

Background - Annual PM2.5 Standard

U.S. EPA set an annual PM2.5 standard in 2012, set at $12 \mu\text{g}/\text{m}^3$

South Coast Air Basin is in “serious” nonattainment, which is the highest classification for PM2.5 standards¹

Coachella Valley is in attainment of this standard

¹ Reclassification from “moderate” to “serious” approved by U.S. EPA effective December 9, 2020 (85 FR 71264)

Annual PM2.5 Trend in the South Coast Air Basin

*Data likely to be approved as exceptional events by U.S. EPA were removed.

Overview of Previous SIP Actions for the 2012 Annual PM2.5 Standard

Attainment plan was included in the 2016 AQMP and submitted to U.S. EPA in 2017

Near roadway data became available in 2020 and showed the highest annual PM2.5 level in the Basin

U.S. EPA requested a supplemental attainment demonstration

The submitted plan was withdrawn in 2023 to avoid potential disapproval*

A revised attainment plan is due to U.S. EPA by December 23, 2024 to avoid sanctions

*U.S. EPA was sued by Center for Biological Diversity in 2023 for its failure to act on the submitted plan

SIP Development Public Process

Spring - Fall
2023

- AQMP & STMPR Advisory Group Meetings

March 2024

- Released Draft Plan for Public Review and Comments

April - May
2024

- Regional Public Hearings

May 2024

- Released Draft Socioeconomic Impact Assessment

June 7, 2024

- Public Hearing for Board consideration

Summer 2024

- CARB adoption and submittal to EPA

For more information, visit

[https://www.aqmd.gov/home/air-quality/air-quality-management-plans/other-state-implementation-plan-\(sip\)-revisions](https://www.aqmd.gov/home/air-quality/air-quality-management-plans/other-state-implementation-plan-(sip)-revisions)

Strategy to Attain Annual PM_{2.5} Standard

NO_x strategy from the
2022 AQMP

Limited controls needed
for PM_{2.5} and precursors

Measures from the 2022 AQMP/SIP that can be Implemented by 2030

South Coast AQMD
stationary source
measures transition to
zero emission where
feasible, lower NO_x
where infeasible

South Coast AQMD
mobile source measures
include incentives and
facility-based measures

CARB will continue to
implement the 2022
State SIP Strategy

Control Measures Identified as Most Stringent Measures (MSM)

- MSM requires all South Coast AQMD rules to be at least as stringent as those in any other air district or state
- Four measures identified that need to be implemented by December 2029

Less residential burning allowed under Rule 445 (Check Before You Burn)

Lower permitting thresholds for confined animal facilities in Rule 223

Lower threshold to require catalytic oxidizers for chain-driven charbroilers in Rule 1138

Require composting of chipped and ground greenwaste prior to land application

Future Emissions

Future Annual PM2.5 Concentrations

* Design value calculated using a hybrid modeling approach

Socioeconomic Impacts

Health Benefits in 2030

Health Outcome	Avoided Incidences	Monetized Value*
Long-Term PM 2.5 Exposure		
Premature deaths avoided, all causes	665	\$8,840
Asthma, New Onset	1,031	\$51
Incidence, Hay Fever/Rhinitis	4,867	\$3
Incidence, Lung Cancer (non-fatal)	57	\$1
Short-Term PM 2.5 Exposure		
Hospital Admission, All Cardiac Outcomes	24	\$1
HA, All Respiratory	69	\$2
Incidence, Ischemic Stroke	37	\$1
Minor Restricted Activity Days	230,393	\$21
Work Loss Days	39,204	\$7

*Millions of 2023 Dollars

- The costs and macroeconomic impacts of the PM2.5 Plan control measures have been analyzed in previous AQMPs
- No additional costs are anticipated in excess of previous analyses
- **\$9B total monetized health benefit annually by 2030**

Staff Recommendation

Adopt the Resolution:

- Determining that the PM2.5 Plan is a later activity within the scope of the Final Program Environmental Impact Report (EIR) for the 2022 AQMP and the Final Program EIR for the 2016 AQMP such that no new environmental document will be required.
- Adopting the PM2.5 Plan and directing staff to submit the adopted PM2.5 Plan to CARB for its approval and subsequent submittal to the U.S. EPA for inclusion into the SIP.

APPENDIX I

Base and Future Year Emission Inventory

CHAPTER 1 - INVENTORY DEVELOPMENT

Background	I-1-1
Air Contaminants	I-1-2
Inventory Source Categories	I-1-34
Stationary Sources.....	I-1-34
Mobile Sources.....	I-1-8

CHAPTER 2 - SUMMARY OF EMISSIONS

Baseline Emission Inventories	I-2-1
Base Year Emissions.....	I-2-1
Future Year Emissions.....	I-2-6
Emission Trend and Agency Responsibilities.....	I-2-54
Condensable and Filterable PM2.5 Emissions	I-2-68
Uncertainty in the Inventory	I-2-71
Controlled Emission Inventories.....	I-2-72
Emissions Reduction from the Proposed Control Measures.....	I-2-72
Emissions Reduction Calculations	I-2-74
CARB Emission Data Reports System	I-2-75

Attachment A: Annual Average Emissions by Source Category in South Coast Air Basin

Attachment B: Annual Average On-Road Mobile Source Emissions in South Coast Air Basin

Attachment C: Diesel Emissions in South Coast Air Basin

Attachment D: Road Construction Dust Emissions in South Coast Air Basin

Attachment E: Emissions of Primary, Condensable and Filterable PM2.5

Chapter 1

INVENTORY DEVELOPMENT

Background

Air Contaminants

Inventory Source Categories

Stationary Sources

Mobile Sources

Background

Federal and State standards limit concentration levels of air contaminants in ambient air to protect public health and welfare. An emission inventory of air pollutants and their sources is essential to identify the major contributors of air contaminants and to identify the measures necessary to reduce air pollution. This Draft PM2.5 Plan includes detailed emissions for base and future milestone years. 2018 is the base year used to project future year emissions for the 2024 PM2.5 Plan and 2030 is the attainment year for the 2012 annual PM2.5 National Ambient Air Quality Standard.

This appendix includes five attachments: Attachment A – Annual Average Emissions Summary by Major Source Category in the South Coast Air Basin (SCAB or Basin); Attachment B – On-Road Emissions by Vehicle Category; Attachment C – Emissions from Diesel Fuel Combustion by Major Source Category; Attachment D – Dust Emissions from Road Construction in SCAB, and Attachment E – Annual Average Emissions Summary for Condensable and Filterable PM2.5 in SCAB. Attachments A through E contain emissions and relevant data for the years of 2018, 2023, 2025, 2028, 2030 and 2031.

Information required to develop the emission inventory is obtained from various programs and rules by South Coast AQMD and other governmental agencies, including the California Air Resources Board (CARB), the California Department of Transportation (Caltrans), and the Southern California Association of Governments (SCAG). Each of these agencies is responsible for collecting data (e.g., industry growth factors, socio-economic projections, travel activity levels, emission factors, emission speciation profiles, and emissions) and developing methodologies (e.g., model and demographic forecast improvements) required to generate a comprehensive emissions inventory. Entire statewide emissions inventories are compiled and maintained by CARB in the California Emission Inventory Development and Reporting System (CEIDARS)¹ and the California Emission Forecasting and Planning Inventory System (CEFIS)². CARB has primary responsibility for developing the emissions inventory for all mobile sources in collaboration with local districts. CARB provides the tool for on-road inventories, the Emission FACTors (EMFAC) 2021³ model, and off-road inventories using models specific to each off-road category⁴. Caltrans provides SCAG with information related to highway projects. SCAG then incorporates these data into their Travel Demand Model for estimating/projecting vehicle miles traveled (VMT) and driving speeds for current and future years. SCAG's socio-economic and transportation activity projections in their 2020 Regional Transportation Plan/Sustainable Communities Strategy (RTP/SCS) are integrated in this Draft PM2.5 Plan. 2020 RTP/SCS is the

latest approved RTP at the time of developing this PM plan. The EMFAC2021 was run with the SCAG custom activities to produce the on-road mobile source inventories.

Air Contaminants

Currently, National Ambient Air Quality Standards (NAAQS), or federal standards, are limited to the following criteria pollutants: ozone (O_3), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), carbon monoxide (CO), fine suspended particulate matter less than 10 microns in diameter (PM₁₀), fine particulate matter less than 2.5 microns in diameter (PM_{2.5}), lead, and sulfate. This appendix presents emission levels for the criteria pollutants and their precursors in the South Coast Air Basin. Specifically, data are included for emissions of total organic gases (TOG), volatile organic compounds (VOCs), oxides of nitrogen (NO_x), oxides of sulfur (SO_x), CO, particulate matter (PM), PM₁₀, PM_{2.5}, and ammonia (NH_3).

TOG incorporates all gaseous compounds containing the element carbon, with the exception of the inorganic compounds, CO, carbon dioxide (CO_2), carbonic acid, carbonates, and metallic carbides. VOCs, a subset of TOG, includes all organic gases in TOG except acetone, ethane, methane, methylene chloride, methylchloroform, perchloroethylene, methyl acetate, para-Chlorobenzo trifluoride (pCBtF), and a number of Freon-type gases. The U.S. EPA definition of VOCs is different from the one used by CARB, which includes some compounds not considered as VOCs by the U.S. EPA. Table I-1-1 lists the compounds that are exempt in the U.S. EPA's VOCs list but are included in CARB's VOCs list. Certain chlorofluorocarbons (CFCs) are still included in CARB's VOCs list. According to CARB, the total VOC emission inventory difference between U.S. EPA and CARB is very small and the added compounds do not have a noticeable contribution to the VOC emission inventory; Those compounds do not impact regional tropospheric ozone and PM formation either.

PM represents all airborne particulate matter, also known as total suspended particles (TSP). PM₁₀ and PM_{2.5} are important subsets of PM. In this ~~Draft~~ PM_{2.5} Plan, the amount of VOC in TOG and the amount of PM₁₀ and PM_{2.5} in PM are calculated for each process primarily using speciation and size fraction profiles provided by CARB.⁵ PM_{2.5} sources include both primary and secondary PM_{2.5} sources. Primary PM_{2.5} is directly emitted from various sources, whereas secondary PM_{2.5} is formed in the atmosphere from chemical reactions involving PM_{2.5} precursor emissions. Potential precursors of secondary PM_{2.5} include NO_x , SO_x , VOC and NH_3 . Furthermore, while air quality standards for NO_x and SO_x are based on NO_2 and SO_2 , respectively, the emissions inventory includes emissions of NO_x and SO_x because multiple species of NO_x and SO_x contribute to the formation of particulate matter, and multiple species of NO_x react with VOCs to produce ozone.

Chemical Abstract Service (CAS) identification numbers have been included for convenience.

(1) Compounds are new since the 2012 AQMP.

(2) Exempt in the consumer product regulation not the architectural coatings suggested control measure.

(3) Recommend exemption for stationary source regulations under South Coast AQMD control.

Inventory Source Categories

Stationary Sources

Stationary sources of emissions are grouped into two categories - point sources and area sources. Point source emissions are from facilities having one or more pieces of equipment registered and permitted with the South Coast Air Quality Management District (AQMD). South Coast AQMD uses permits to collect facility emission-related information for those sources such as facility location in latitude and longitude, chimney stack height, and plume exit temperature. Area source emissions are from numerous small facilities or pieces of equipment, such as gasoline-dispensing facilities, residential water heaters, consumer products and architectural coatings, for which locations may not be specifically identified. For modeling purposes, area source emissions are spatially allocated to grid cells using demographic data as surrogates (e.g., population, housing, and land use).

Point Sources

The point source emission inventory for 2018 is based on the emissions data reported by facilities in the calendar year 2018 via the South Coast AQMD's Annual Emissions Reporting (AER) Program. This program applies to facilities emitting 4 tons per year (TPY) or more of VOCs, NO_x, SO_x, or PM or emitting more than 100 TPY of CO, as specified in Rule 301(e). Facilities subject to the AER Program calculate or measure their emissions and report them. If calculated, they are primarily based on their throughput data (e.g., fuel usage, material usage), appropriate emission factors or source tests, and control efficiency (if applicable). Under the calendar year 2018 AER Program, approximately, 1,596 facilities reported their annual emissions to the South Coast AQMD. Smaller industrial facilities with emissions below reporting thresholds are not subject to the AER program, but emissions from those facilities are included in the area source inventory.

In order to prepare the point source inventory, emissions data for each facility were categorized based on the U.S. EPA's Source Classification Codes (SCCs) for each emission source category. Since the AER program collects emissions data on an aggregate basis (i.e., similar equipment and processes with the same emission factor are grouped and reported together), facility's equipment permit data were used in conjunction with the reported data to assign the appropriate SCC codes and develop the inventory at the SCC level. Air quality modeling uses specific facility locations provided in latitude and longitude coordinates. Business operation activity profiles are also recorded to allocate the annual emission to finer time resolutions (e.g., hourly, day of the week, and monthly emission rates). The facility business type is assigned to facilities based on North American Industry Classification System (NAICS) Codes according to their primary activity. Growth projections are assigned by NAICS using socioeconomic indexes provided by the SCAG 2020 RTP/SCS.

Area Sources

The South Coast AQMD and CARB shared responsibility for developing the 2018 area source emissions inventory for approximately 400 area source categories. The South Coast AQMD developed the area source inventory for about 150 categories, while CARB developed the remaining area source categories such as consumer products and degreasing. For each area source category, a specific methodology is used to estimate emissions. Using revised data such as throughput, activity, consumption, various demographic data, and recently adopted regulations, the following categories were updated: consumer products, architectural coating, adhesive and

sealants, composting, natural gas and LPG combustion sources, LPG transfer dispensing fugitive loss, paved and unpaved road dust, and livestock.

Rule Implementation

The cutoff dates for regulations on stationary sources included in the baseline emissions are the same as in the 2022 AQMP. All rules adopted since the 2016 AQMP by October 2020 and Rule 1109.1 were included in the baseline and are listed in Table I-1-2A (NO_x regulations) and Table I-1-2B (VOC and PM regulations). Since the adoption of the 2016 AQMP and through the cutoff dates, a total of 14 source-specific rules were adopted or amended, that would achieve up to 6.6 tons per day NO_x reductions by the milestone year of 2025. Rule 1109.1, amended in November 2021, is expected to achieve 3.94 tons per day NO_x reductions by 2030 in addition to the reductions associated with declining RECLAIM allocation cap as defined in the Rule 2002. While the baseline emissions from the RECLAIM universe are the same as the baseline emissions included in the 2022 AQMP, this plan quantifies additional adjustments to RECLAIM sources as a result of recently approved regulations and their associated emission reductions are included in the attainment demonstration. NO_x emission reductions from RECLAIM sources and these additional adjustments are discussed in detail in Chapter 3 of this Plan and in Chapter 2 of this Appendix.

TABLE I-1-2A
2016 AQMP NOX EMISSION REDUCTIONS IN TONS PER DAY BY MEASURE/ADOPTION DATE FROM SOUTH COAST AQMD MEASURES

Measure	2016 AQMP Measure	Adopted	2025	
			Commitment ^c	Expected Reductions from the Implementation
Rule 1135 ^a – Electricity Generating Facilities	CMB-05	2018	5	0.36
Rules 1146, 1146.1, 1146.2 ^b – Industrial/Commercial Boilers, Steam Generator and Process Heaters	CMB-05	2018		0.39
Rule 1118.1 ^a – Non-Refinery Flares	CMB-05	2019		0.16

Mobile Sources

On-Road Mobile Sources

The Draft PM_{2.5} Plan emission estimates for on-road motor vehicles are derived by applying emission rates from CARB's EMFAC2021⁷ model to the transportation activity data provided by SCAG in its adopted 2020 RTP/SCS. The California Department of Transportation (Caltrans), the Department of Motor Vehicles (DMV), and SCAG supply CARB with necessary data to develop the on-road mobile source emissions inventory. The California DMV maintains a count of registered vehicles and Caltrans provides highway network, traffic counts, and road capacity data. SCAG maintains the regional transportation model containing the temporal and spatial distribution of motor vehicle activities (including travel time, travel speed, and volume of traffic for AM-peak, mid-day, PM-peak, evening and night hours). In addition, SCAG periodically conducts origin and destination surveys to validate the regional transportation model and updates the demographic database of population, housing, employment, and land use patterns within its jurisdiction.

Emission rate data in EMFAC2021 are collected from various sources, such as individual vehicles in a laboratory setting, tunnel studies and certification data, etc. Vehicle activity data are obtained from regional planning agencies, such as SCAG. The EMFAC2021 model calculates exhaust and evaporative emission rates by vehicle type under different vehicle speeds and environmental conditions (e.g., temperature and relative humidity). Temperature and humidity profiles are used to produce month specific, annual average, and episodic inventories.

Parameters considered by the EMFAC2021 include the type of emissions control technology, fuel type, distribution of operating speeds, speed and temperature correction factors, and the reduction in emissions resulting from the State's motor vehicle regulatory programs.

The EMFAC2021 Model includes the following mobile source data:

- (1) Thirteen vehicle classes (passenger cars, light-duty trucks under 3,750 pounds, light-duty trucks between 3,750 pounds and 5,750 pounds, medium-duty trucks between 5,751 pounds and 8,500 pounds, light-heavy-duty trucks between 8,501 pounds and 10,000 pounds, light-heavy-duty trucks between 10,001 pounds and 14,000 pounds, medium-heavy-duty trucks between 14,001 pounds and 33,000 pounds, heavy-heavy-duty-trucks for over 33,000 pounds, motor homes, motorcycles, school buses, urban buses, and other buses)
- (2) Five vehicle fuel types (gasoline, diesel, natural gas, electric and plug-in hybrid)
- (3) Truck types (ports, agriculture, construction, interstate, out-of-state, public fleet, utility fleet, power take off, and tractor)
- (4) In-state and out-of-state
- (5) Fifty calendar years (2000-2050)
- (6) Two vehicle exhaust processes (starts and running)

⁷ https://ww2.arb.ca.gov/sites/default/files/2021-08/emfac2021_technical_documentation_april2021.pdf

- (7) Four evaporative processes (diurnal, hot soak, running loss, and resting loss)
- (8) Twelve pollutants (TOG, ROG, CO, CO₂, CH₄, N₂O, NO_x, PM, PM₁₀, PM_{2.5}, NH₃, and SO_x)
- (9) Fuel consumption and energy consumption for electric VMT.

To develop the detailed emission inputs needed by air quality chemical transport models, such as the Community Multi-scale Air Quality model (CMAQ), emissions from on-road motor vehicles are estimated at the grid level using the emission processing tool Emissions Spatial and Temporal Allocator (ESTA). ESTA is a command-line tool for processing raw emissions data into spatially and temporally allocated emissions inventories, making them suitable for photochemical modeling or other analysis. ESTA is an open-source, Python-based tool designed by the Air Quality Planning and Science Division (AQPSD) branch of CARB.⁸

EMFAC2021 includes more subcategories for some of the major vehicle class categories (i.e., medium-heavy-duty diesel trucks and heavy-heavy diesel trucks) based on their weights (heavy or small), types (agricultural, construction, CA international registration plan), road type (in-state or out-of-state), etc. However, the on-road mobile sources emissions in the Draft PM2.5 Plan are reported by major vehicle class categories to compare with previous inventory reporting.

EMFAC2021 was the basis for on-road planning inventories, emission budgets, and rate-of-progress calculations. The EMFAC2021 model has undergone extensive revisions from the previous version (EMFAC2017) to make it more user-friendly and flexible as well as to allow incorporation of larger amounts of data demanded by the current regulatory and planning processes. In addition to the model structural changes, other updates include:

- New data and significant changes to the methodologies regarding calculation of motor vehicle emissions and revisions to implementation data for control measures;
- New methodologies for brake and tire wear and evaporative emissions;
- New approaches to light-duty activity forecasting, using up-to-date modeling approaches from academic and government agencies to assess historic trends in multiple economic indicators to forecast future vehicle activity, alongside novel forecasting frameworks for heavy duty VMT and light duty ZEV sales;
- Updated emissions factors and data on car and truck activities, and emissions reductions associated with new regulations supporting new estimates of emissions from heavy-heavy duty diesel trucks and buses. New emission factors were developed based on data from the U.S. EPA's In-Use Vehicle Program, CARB's Vehicle and Truck and Bus Surveillance Programs, CARB's Portable Emissions Measurement Systems (PEMS), and Transit Bus testing, dynamometer and Portable Emission Measurement Systems Data;
- Updated motor vehicle fleet age, vehicle types, and vehicle population based on 2013-2019 California Department of Motor Vehicle (DMV) data, International Registration Plan (IRP) data, Truck Regulation Upload, Compliance, and Reporting System (TRUCRS) data, Port Vehicle Identification Number (VIN) data, California

⁸ https://github.com/mmb-carb/ESTA_Documentation.

Highway Patrol School Bus Inspections, and National Transit Database information. Each of these changes affect emission factors for each area in California.⁹

Figure I-1-1 compares on-road baseline emissions estimated by EMFAC2017, which are used in the 2022 AQMP, with those estimated by EMFAC2021, which are used in the ~~Draft 2024 PM_{2.5} Plan~~ PM_{2.5} Plan. Both sets of emission estimates use the same travel activity data from the 2020 RTP/SCS. The figure includes emissions for base year 2018 and selected future milestone years: 2023, 2025, 2028, 2030, and 2031. The comparison of on-road emissions reflects changes due to the updated EMFAC model. EMFAC2021 is the most recent version of EMFAC that is approved by U.S. EPA, and it provides the basis of the ~~Draft 2024 PM_{2.5} Plan~~ PM_{2.5} Plan on-road emission estimates. The values shown in Figure I-1-1 reflects reductions from heavy-duty vehicle inspection and maintenance (HD I/M) regulation.

For year 2018, EMFAC2021 estimates notably higher VOC and NO_x emissions, and lower emissions of PM_{2.5} than EMFAC2017. Estimates of NO_x and VOC in EMFAC2021 are higher than in EMFAC2017 because newer vehicle test data show that light-duty vehicles have higher exhaust emissions, and updated DMV data for 2018 indicate that medium heavy-duty trucks are older than what was assumed in EMFAC2017. PM_{2.5} emissions are substantially reduced in EMFAC2021 with respect to EMFAC2017, as a result of updates on emissions and speed correction factors for brake wear obtained from newer emission testing. The differences in VOC and PM_{2.5} emissions are propagated through 2030, whereas NO_x emissions only differ slightly between EMFAC2017 and EMFAC2021.

Emissions in future milestone years are significantly lower than the base year 2018 emissions for all pollutants except for ammonia. These emission reductions in the future can be attributed to the ongoing implementation of regulations and programs, such as Advanced Clean Cars Program¹⁰, ICT Regulation, Zero Emission Airport Shuttle Bus Regulation¹¹, Clean Miles Standard¹², ACT, and HD Omnibus low NO_x requirements. Despite the growth in vehicular activities, emissions from on-road mobile sources are expected to decrease in future years, with NO_x and VOC emissions in 2030 projected to be 73 and 49 percent lower than those in 2018, respectively. Emissions of NH₃ from both gasoline and diesel vehicles are projected to increase in the future. NH₃ emissions from gasoline vehicles are produced as a reaction in the catalytic converter. NH₃ emitted by heavy-duty diesel trucks originates from the use of selective catalytic reactors (SCR) to control NO_x emissions from diesel vehicles. Ammonia emissions from SCR systems is generally referred to as *ammonia slip*. SCR technology reduces NO_x emissions by converting them into harmless nitrogen and water vapor through a reaction with ammonia. However, if the SCR system injects more ammonia than required for the NO_x reduction process, or if the catalyst becomes inefficient, unreacted ammonia can escape into the exhaust stream. The projected increase in vehicle activity for light-, medium- and heavy-duty vehicles leads to the increase in NH₃ emissions.

COMPARISON OF ON-ROAD EMISSIONS OF BASE AND FUTURE MILESTONE YEARS USING EMFAC 2017 VERSUS
EMFAC 2021
(ANNUAL AVERAGES)

Off-Road Mobile Sources

Mobile sources not included in the on-road mobile source emissions inventory are classified as off-road mobile sources. CARB uses a number of models to estimate emissions for more than one hundred off-road equipment categories. The models account for the effects of various adopted regulations, technology types, and seasonal effects on emissions. The models combine population, equipment activity, horsepower, load factors, population growth, retirement factors, and emission factors to yield annual emissions by county, air basin, or Statewide. Temporal usage profiles are used to develop seasonal emission estimates, which are then spatially allocated to counties or air basins using surrogates such as population.¹³ The emissions presented here are consistent with the off-road emissions developed for the 2022 AQMP¹⁴, except for a small change in construction equipment emissions. After the development of the 2022 AQMP, an error was discovered in the emission allocations for in-use emissions from off-road construction equipment in Riverside County. This error only affected future year emissions and is now corrected in this Draft PM2.5 Plan.

¹³ More information about off-road models can be found at http://www.arb.ca.gov/msei/categories.htm#offroad_motor_vehicles

Baseline Emission Inventories

Base Year Emissions

Table I-2-1A compares the annual average emissions in the 2022 AQMP base year inventory and the emissions estimated in the Draft PM2.5 Plan for all PM2.5 precursors. As described above, the differences between the 2022 AQMP and the Draft PM2.5 Plan are from on-road sources due to the transition from EMFAC2017 to EMFAC2021. Overall, the base year 2018 emissions of VOC, NOx, and SOx in the Draft PM2.5 Plan are higher than those in the 2022 AQMP by 4%, 5% and 1%, respectively. In contrast, direct PM2.5 emissions in the Draft PM2.5 Plan are 9% lower than the 2022 AQMP.

Table I-2-1B shows the 2018 annual average emissions inventory by major source category. Stationary sources are further divided into point sources (e.g., petroleum production and electric utilities) and area sources (e.g., architectural coatings, residential water heaters, consumer products, and permitted sources smaller than the emission reporting threshold – generally 4 tons per year). Mobile sources consist of on-road (e.g., passenger cars and heavy-duty trucks) and off-road sources (e.g., locomotives and ships).

Figure I-2-1 illustrates the relative contribution of each source category to the 2018 inventory. VOC and NH3 emissions are both largely driven by area sources, although specific area sources differ for the two pollutants. Area sources account for half of the total VOC emissions, with consumer products alone accounting for 27% of total VOC emissions. For NH3 emissions, humans and pets contribute to half of the total area source emissions, and overall, area sources contribute to 70% of the total NH3 emissions. Mobile sources are the top contributor to NOx emissions, whereas area sources are the top contributor to PM2.5 emissions. Overall, total mobile source emissions account for almost 45% of VOC emissions and 85% of NOx emissions. The on-road mobile category alone contributes over 23% and 49% of VOC and NOx emissions, respectively. For directly emitted PM2.5, mobile sources represent 18% of total emissions, with an additional 15% from vehicle-related entrained dust from paved and unpaved roads. Non-vehicle related area sources, such as commercial cooking and residential fuel combustion, are the predominant source of directly emitted PM2.5 emissions, contributing 46% of total emissions. Stationary sources are responsible for most of the SOx emissions in the Basin, with the point source category (larger facilities subject to AER requirements) contributing 49% of total SOx emissions, whereas off-road mobile sources, mainly ocean-going vessels (OGV) and aircraft, contribute to 26% of total SOx emissions.

Figure I-2-2 shows the fraction of the 2018 inventory by responsible agency. The U.S. EPA, CARB, and South Coast AQMD split regulatory authority over these pollutants, with the U.S. EPA and CARB primarily responsible for mobile sources. Specifically, the U.S. EPA's authority applies to aircraft, locomotives, OGVs, military harbor craft, and other mobile categories, including California international registration plan (CAIRP) and out-of-state (OOS) medium- and heavy-duty trucks and pre-empt off-road equipment with less than 175 horsepower. CARB regulates other mobile sources, consumer products, and portions of area sources related to fuel combustion, and petroleum production and marketing. The South Coast AQMD has limited authority over mobile sources, which it exercises via fleet rules and facility-based mobile source measurements. On the other hand, it exercises authority over most area sources and all point sources. The same figure also illustrates agency responsibility as it pertains to VOC, NOx, SOx, NH3, and directly emitted PM2.5 emissions. NOx and VOCs are

important precursors to ozone and PM_{2.5} formation, and SO_x, NH₃ and directly emitted PM_{2.5}. As shown, most NO_x and VOC emissions in the Basin are from sources that fall under the primary jurisdiction of the U.S. EPA or CARB. For example, 84% of NO_x and 74% of VOC emissions are from sources primarily under CARB and the U.S. EPA control. Conversely, 61% of SO_x emissions, 76% of NH₃ emissions, and 81% of directly emitted PM_{2.5} emissions are from sources under the South Coast AQMD control. This underscores the need for coordinated actions at the local, state, and federal levels to ensure that the region attains the federal ambient air quality standards.

TABLE I-2-1A
COMPARISON OF 2018 EMISSIONS
BETWEEN THE 2022 AQMP AND THE DRAFT 2024 PM_{2.5} PLAN (TONS PER DAY)

	On-Road Vehicles	Total Emissions

(Annual Average)

Future Year Emissions

Future baseline emissions, which assume no additional air quality regulations introduced beyond those already adopted regulations and programs, are presented in this appendix. The future years include the attainment year and other milestone years significant to demonstrate progress toward attainment. They are 2023, 2025, 2028, 2030 and 2031. Emissions by major source category are provided in Attachment A. These emissions are forecasted from the 2018 base year by incorporating the controls implemented under South Coast AQMD rules and programs adopted as of October 2020, CARB rules adopted by December 2021, and a specific set of growth rates from SCAG for population, industry, and motor vehicle activity. South Coast AQMD's Rule 1109.1- Emissions of Oxides of Nitrogen from Petroleum Refineries and Related Operations, which was adopted in November 2021, is also reflected in this Draft PM2.5 Plan emissions inventory. Emission reductions from CARB's Heavy-Duty Inspection and Maintenance (HD I/M)¹⁵ adopted in December 2021 are not embedded in EMFAC2021 but were reflected in the baseline emissions using an off-EMFAC model adjustment. Growth projections from SCAG were replaced in certain categories where more specific information was available to improve emission forecasts. For example, District-wide natural gas consumption forecasts, consistent with the 2020 California Gas Report,¹⁶ were used to estimate the area source emissions associated with natural gas combustion.

The methodology used to forecast emissions for non-RECLAIM sources is described in the following sections. Baseline emissions for future years are obtained using the following equation:

$$FY_i = BY \times CF_i \times GF_i$$

where FY_i is the forecasted emissions of an air pollutant in the Basin for a future year i . BY refers to the base year (2018) emissions of the air pollutant. The control factor, CF_i , is an indicator of the level of control on a specific source category as a result of adopted state and local air quality regulations in year i . GF_i is a growth factor determined for different categories of industry with socioeconomic data for year i with respect to base year. Both CF_i and GF_i are unitless factors that reflect a change with respect to the base year 2018.

For RECLAIM sources, baseline emissions are the same as the baseline emissions included in the 2022 AQMP. The RECLAIM allocation cap defined in the South Coast AQMD's rule 2002 was used for years prior to the conversion to a traditional command and control structure. After the sunset year, sources belonging to the RECLAIM universe, referred to as "former-RECLAIM", are then scaled using growth and control factors normalized by the growth and control factors of the sunset year. Baseline emissions for years after sunset are projected as follows:

$$FY_i = SY \times CF_i/CF_s \times GF_i/GF_s$$

¹⁵ Heavy-Duty Inspection and Maintenance Program, <https://ww2.arb.ca.gov/our-work/programs/heavy-duty-inspection-and-maintenance-program>

¹⁶ https://www.socalgas.com/sites/default/files/2020-10/2020_California_Gas_Report_Joint_Utility_Biennial_Comprehensive_Filing.pdf.

where FY_i is the forecasted emissions for year i . SY is the emissions in the sunset year. CF_i is the control factor for year i , and CF_S is the control factor in the sunset year. GF_i is the growth factor for year i and GF_S is the growth factor in the sunset year.

In the 2022 AQMP, it was assumed that 2025 and 2026 would mark the initial years without RECLAIM programs for NOx and SOx, respectively, based on the best available information at the time of plan development. However, during the development of the RECLAIM landing rules, the sunset timeline was revised, delaying the sunset of the NOx RECLAIM program by one year to 2026, and placing the sunset of the SOx RECLAIM program on hold to accommodate operational requirements and stakeholder feedback. The change in the sunset year for NOx is not expected to affect the attainment demonstration, because landing rules are effectively implemented prior to 2030 and the reductions anticipated for 2030 are not impacted by the change of the sunset schedule. The change in sunset for SOx will ensure that the SOx emissions remain below the cap, and thus, does not affect the PM2.5 attainment strategy.

Control Factors

The impacts of South Coast AQMD rules and programs adopted or amended with compliance dates after 2018 are included in the baseline emission forecasts using control factors. Control factors were developed with reference to 2018 and applied to source categories and/or specific industries affected by the adopted rules/amendments. For industrial sources, the standard industrial codes (SIC) system is used. The U.S. EPA's SCC system is used for equipment. A control factor, CF_i , is calculated with the following equation for each individual source category:

$$CF_i = 1 - \text{Control Efficiency}$$

Control efficiency is mostly based on estimates projected during rulemaking. Control factors represent the remaining emissions after a rule or regulation is implemented after 2018. Table I-2-2A lists control factors for the year 2025 and the attainment year 2030 for South Coast AQMD rules for non-RECLAIM sources amended or adopted between the adoption of the 2016 AQMP and the cutoff dates for this Plan, and that have post-2018 compliance dates. Table I-2-2B lists the resulting future accumulated annual average emission reductions in 2025 and 2030. In total, eleven regulations and a Facility Based Mobile Source Measure for Commercial Airports were amended or adopted by South Coast AQMD since the development of the 2016 AQMP, and they are reflected in the baseline emissions inventory of this Draft PM2.5 Plan.

Table I-2-2C lists the South Coast AQMD's regulations to convert the RECLAIM program to a traditional command-and-control structure. As of September of 2023, South Coast AQMD has adopted eleven so-called 'landing' rules to transition out of RECLAIM program to a traditional command-and-control structure. A portion of R1109.1 (2.35 tons per day NOx reduction) implements Rule 2002, therefore it was counted toward the RECLAIM cap "shave". The reductions attributed to the non-shave portion of Rule 1109.1, which amount to 3.94 and 4.65 tons per day by 2030 and 2037, respectively, are already reflected in the baseline emissions (and not included in Table I-2-2C). In contrast, the remaining landing rules were not included in the baseline. At the time of the 2022 AQMP development, many of these rules were still in progress, and it was uncertain whether

the reductions would be considered part of the RECLAIM shave. To prevent double counting, the reductions from the landing rules were assumed to be included in the RECLAIM shave in the 2022 AQMP. Subsequently, the majority of the landing rules have been adopted, and they are expected to achieve reductions exceeding the requirements of the RECLAIM shave over a longer timeframe. Given the maturity of the RECLAIM shave in 2022, any reductions in excess of the 2022 reductions are considered new reductions. Consequently, the net NO_x reductions from landing rules beyond the shave are projected to be 2.86 tons per day by 2030, as shown in Table I-2-2C.

Figure I-2-3 shows the (former-) RECLAIM universe NO_x emission trend in the baseline for the Draft PM_{2.5} Plan SIP inventory for future years (which is the same as in the 2022 AQMP) and the adjusted future RECLAIM emissions that result from the quantification of all landing rules. The latest amendment of the Rule 2002 in December 2015 reduces NO_x allocation cap for RECLAIM facilities from 26.5 tons per day in 2015 to 14.5 tons per day in 2022. The 2018 emissions are reported emissions which are smaller than the allocation cap, 23.5 tons per day, for that year. In the RECLAIM baseline emissions for this Plan, the NO_x emissions under former-RECLAIM undergo a steady decrease with the implementation of R1109.1 from 2025 to future years. With the additional adjustment to the RECLAIM universe, RECLAIM NO_x emissions in 2030 are reduced by 2.86 tons per day with respect to the baseline (consistent with Table I-2-2C). This adjustment to RECLAIM emissions is not included in the baseline, but it is included in the attainment strategy in this Plan for 2030.

There are several stationary rules for non-RECLAIM sources adopted or amended after the cut-off date of this Plan (October 2020 except for R1109.1). Table I-2-2D lists the resulting future accumulated annual average emission reductions in 2030. R1111 was amended in January 2023 to update the implementation schedule with the full implementation year revised to 2048 with the same net reductions. R1168 was amended in November 2022 to revise the emission reductions. R1147, R1147.2 and R1150.3 are newly adopted or amended rules that have quantified emission reductions in milestone years for this plan, although those reductions were not reflected into the baseline emissions. As in the case of the RECLAIM adjustment, the emission reductions from these newly adopted or amended rules are included in the attainment strategy in this Plan for 2030.

TABLE I-2-2A
CONTROL FACTORS[±] BY SOUTH COAST AQMD RULES APPLYING TO NON-RECLAIM SOURCES
WITH POST-2018 COMPLIANCE DATES

RULES	DESCRIPTION	Adoption /Amend Date	2025			2030

^aR1111 reduction reflect the implementation schedule for the March 2018 amendment.

^bThe emission reductions for RECLAIM portion are not included to avoid double counting.

TABLE I-2-2C
REDUCTIONS IN TONS PER DAY FROM SOUTH COAST AQMD'S REGULATIONS TO CONVERT THE RECLAIM PROGRAM TO A COMMAND-AND-CONTROL STRUCTURE

Adopted/Amended Date	District Rule	Implementation Schedule		Total Reductions from RECLAIM Sources in 2030 (tpd)	2030 Reduction in excess of 2022 reductions (tpd)
		Start Year	End Year		
11/1/2019	Rule 1110.2 – Control of Emissions from Gaseous- and Liquid-fueled Engines	2020	2029	0.25	0.21
1/4/2019	Rule 1118.1 – Control of Emissions from Non-Refinery Flares	2022	2025	0.03	0.03
4/5/2019	Rule 1134 – Emissions of Oxides of Nitrogen from Stationary Gas Turbines	2024	2027	1.66	1.66
11/2/2018	Rule 1135 – Electricity Generating Facilities	2020	2025	0.30	0.18
12/7/2018	Rule 1146 & 1146.1 – Emissions of Oxides of Nitrogen from Industrial, Institutional, Commercial Boilers, Steam Generators, and Process Heaters	2019	2033	0.36	0.08
12/7/2018	Rule 1146.2 – Emissions of Oxides of Nitrogen from Large Heaters and Small Boilers and Process Heaters	2022	2023	0.002	0.002
5/6/2022	Rule 1147 – NOx Reductions from Miscellaneous Sources	2024	2059	0.40	0.40
8/6/2021	Rule 1147.1 – NOx Reductions from Aggregate Dryers	2025	2057	0.01	0.01
4/1/2022	Rule 1147.2 – NOx Reductions from Metal Melting and Heating Furnaces	2026	2057	0.49	0.36
8/4/2023	Rule 1153.1 – Emissions of Oxides of Nitrogen from Commercial Food Ovens	2024	2036	0.02	0.02
Cumulative reductions from the landing rules listed above*				3.47	2.86

* Reductions are calculated for each rule individually. Because some sources are affected by more than one rule, the compounded emission reductions are slightly lower than the sum of reductions from individual rules.

FIGURE I-2-3
NOX EMISSION OF (FORMER-) RECLAIM SOURCES FOR FUTURE YEARS IN THE DRAFT PM_{2.5} BASELINE AND ADJUSTED RECLAIM EMISSIONS AS A RESULT OF QUANTIFIED LANDING RULES

**TABLE I-2-2D
ACCUMULATED EMISSION REDUCTIONS IN TONS PER DAY BY POST-2022 AQMP SOUTH COAST AQMD
RULES FOR NON-RECLAIM SOURCES**

Adoption Date	District Rule	Implementation Schedule		Net SIP Reduction by 2030* (tpd)
		Start Year	End Year	
9/1/2023	Rule 1111 – Reduction of NOx Emissions from Natural-Gas-Fired, Fan-Type Central Furnaces	2012	2050	-0.07**
5/6/2022	Rule 1147 – NOx Reductions from Miscellaneous Sources	2024	2059	0.28
8/6/2021	Rule 1147.1 – NOx Reductions from Aggregate Dryers	2025	2057	0.01
4/1/2022	Rule 1147.2 – NOx Reductions from Metal Melting and Heating Furnaces	2026	2057	0.06
2/5/2021	Rule 1150.3 – Emissions of Oxides of Nitrogen from Combustion Equipment at Landfills	2021	2031	0.04
8/4/2023	Rule 1153.1 – Emissions of Oxides of Nitrogen from Commercial Food Ovens	2024	2036	0.02
11/4/2022	Rule 1168 – VOC reductions from adhesive and sealant applications	2017	2028	-0.14**

*Reductions by 2030 for each rule are calculated with SIP baseline inventory and associated control factors based on rule-specific implementation schedules.

**The amendment allowed more time to comply with the rule requirements, which resulted in less reductions in 2030 than the earlier version. Negative values indicate the changes from the previous version reflected in the 2022 AQMP.

Growth Factors

To quantify growth, a facility business type is assigned to each facility based on the North American Industry Classification System (NAICS) Code according to their primary activity. Growth projections by NAICS are based on SCAG's 2020 RTP/SCS. The growth scalars were developed using the most recent data from Energy Information Administration (EIA), Southern California Gas Company, Bureau of Land Management (BLM), and South Coast AQMD rule compliance records.

Each emission inventory source grows based on its growth surrogate. These growth surrogates include industry output growth, employment growth, demographic growth, vehicle miles traveled (VMT) growth, and others. The demographic forecasts from the year 2018 through 2031 for population, housing, employment, and motor vehicle activity are shown in Table I-2-3. Current forecasts indicate that this region will experience a 7.9 percent population growth by the year 2030 with a 1.8 percent increase in vehicle miles traveled (VMT) from the 2018 levels. Housing units and total employment are projected to grow by 11.7 percent and 7.3 percent, respectively. Table I-2-4 shows the relative distribution of population by county in the Basin for the years 2018, 2023, 2025, 2028, 2030 and 2031. By 2031 the populations in Los Angeles and Orange counties are projected

to increase by 9 percent from the 2018 levels, compared with the increases for Riverside and San Bernardino counties of 23 percent and 19 percent, respectively, indicating faster growth in inland counties than Los Angeles and Orange counties.

The selection of the surrogate by which emission growth is projected depends on the type of activity. For instance, manufacturing sectors use output growth as a surrogate. Output growth is the product of employment and productivity. Employment growth is chosen for labor intensive sectors, such as construction and laundering. Certain emission sources use demographic data as their surrogate; for example, the number of housing units is used to project emissions from architectural coatings, and population growth is used for the composting waste disposal category. Some growth projections are from SoCalGas 2020 Gas Data Report for natural gas combustion related categories. Growth factors for specified ranges of NAICS categories were projected by SCAG and are based on predictions of growth for different industrial sectors in each county. SCAG has provided growth factors for future milestone years such as 2023, 2025, 2028, 2030, and 2031. Table I-2-5 lists the point sources growth surrogate by NAICS. Table I-2-6 shows the area sources growth surrogate by source category. Tables I-2-7 through Table I-2-11 illustrate the growth factors for point sources by NAICS for years of 2023, 2025, 2028, 2030, and 2031 in the Draft PM2.5 Plan. Tables I-2-12 through Table I-2-16 contain the growth factors for years of 2023, 2025, 2028, 2030, and 2031 in the Draft PM2.5 Plan for the area sources by source category.

TABLE I-2-6
AREA SOURCES GROWTH SURROGATE BY SOURCE CATEGORY

SOURCE DESCRIPTION	SURROGATE
Cogen	SCG-Cogen*
Gaseous Fuel	NAICS 211 Output
Ind. Stationary IC Engines - Natural Gas	SCG - Industrial Combustion*
Industrial Natural Gas (Unspecified)	SCG - Industrial Combustion*
Industrial LPG Combustion	Manufacturing Output
Industrial Distillate Oil Combustion	Manufacturing Output
Ind. Stationary IC Engines - Other Fuel	Manufacturing Output
Ag Irrigation IC Engines-Stationary	CARB Growth Data
Ag Irrigation IC Engines-Portable	CARB Growth Data
Commercial Space Heating	SCG - Commercial Space*
Commercial Water Heating	SCG - Commercial Water*
Commercial Combustion – Internal	SCG - Commercial Combustion*
Commercial Combustion – External	SCG - Commercial Combustion*
Commercial LPG Combustion	Service Output
Stationary Engines – Diesel	CARB Growth Data
Resource Recovery	SCG-Cogen*
Sewage Treatment Plants - POTWs - Ammonia	Population
Municipal Waste Disposal	Population
Composting – Ammonia	No Growth
Biological Waste – Composting	Population
Laundering	Total Employment
Degreasing	Manufacturing Output
Auto Refinishing	Misc. Services Employment
Marine Coating	Water Transportation Output
Paper Coating	Paper Manufacturing Output
Fabric Coatings	Textile Output
Can and Coil Coatings	Fabricated Metal Output
Metal Part and Products Coatings	Fabricated Metal Output
Wood and Fabricated Furniture Coatings	Furniture Output
Plastic Parts Coatings	Plastic Output
Semiconductor Coatings	Computer Output
Aircraft and Aerospace Coatings	Air Transportation Output
Thinning and Cleanup Solvent Use	Manufacturing Output

TABLE I-2-6 (CONTINUED)
AREA SOURCES GROWTH SURROGATE BY SOURCE CATEGORY

SOURCE DESCRIPTION	SURROGATE
Printing	Printing Output
Adhesive and Sealants (Solvent Based)	Manufacturing Output
Adhesive and Sealants (Water Based)	Manufacturing Output
Miscellaneous Industrial Solvents	Manufacturing Output
Oil Production Fugitive	NAICS 211 Output
Natural Gas Transmission Losses	SCG - Total - Natural Gas*
LPG Transfer and Dispensing - Fugitive Losses	Households
Gasoline Dispensing Tank-Working Losses	Gasoline Consumption
Gasoline Dispensing Tank-Breathing Losses	Gasoline Consumption
Vehicle Refueling-Vapor Displacement Losses	Gasoline Consumption
Vehicle Refueling-Spillage	Gasoline Consumption
Storage Tank and Pipeline Cleaning	Gasoline Consumption
Tank Cargo-Pressure Related Fug. Losses	Gasoline Consumption
Tank Cargo-Vapor Hose Fugitive Losses	Gasoline Consumption
Tank Cargo-Product Hose Fugitive Losses	Gasoline Consumption
Bulk Gasoline Storage and Transfer (Unspec)	Gasoline Consumption
Rubber and Rubber Products	Plastic Output
Fiberglass and Fiberglass Products	Plastic Output
Plastic and Plastic Products	Plastic Output
Wine Fermentation	Beverage Manufacturing Output
Wine Aging	CARB Growth Data
Bakeries	Food Output
Agricultural Products Processing Losses	Agriculture Output
Agricultural Crop Processing Losses	Agriculture Output
Sand and Gravel Excavation	Mineral Product Output
Asphaltic Concrete Production	Construction Employment
Grinding/Crushing of Aggregates	Mineral Product Output
Surface Blasting	Mining Extraction Output
Cement Concrete Manufacturing and Fabrication	Mineral Product Output
Open Pile Storage	No Growth
Other Mineral Processes	Mineral Product Output
Secondary Metal Production	Primary Metal Output
Wood Product Losses	Furniture Output

TABLE I-2-6 (CONTINUED)
AREA SOURCES GROWTH SURROGATE BY SOURCE CATEGORY

SOURCE DESCRIPTION	SURROGATE
Industrial Lubricant	Population
Industrial Process Losses (Unspecified)	No Growth
Consumer Products (Except Aerosol)	Population
Aerosol Consumer Product – Aerosol	No Growth
Architectural Coatings	Households
Ag Pesticides Methyl Bromide	CARB Growth Data
Ag Pesticides non-Methyl Bromide	CARB Growth Data
non-Ag Pesticides-Methyl Bromide	CARB Growth Data
non-Ag Pesticides-non-Methyl Bromide	CARB Growth Data
Agricultural Fertilizer – Ammonia	CARB Growth Data
Asphalt Paving	Construction Employment
Residential Wood Stoves	No Growth
Residential Wood Fireplaces	No Growth
Residential Natural Gas Space Heating	SCG - Residential Space*
Residential Distillate Oil Combustion	Households
Residential Natural Gas Water Heating	SCG - Residential Water*
Residential Natural Gas Cooking	SCG - Residential Cooking*
Residential Natural Gas Comb – Other	SCG - Residential Combustion*
Residential LPG Combustion	Households
Farming Operations	CARB Growth Data
Residential Building Construction - Dust	Construction Employment
Commercial Building Construction - Dust	Construction Employment
Industrial Building Construction – Dust	Construction Employment
Institutional Building Construction - Dust	Construction Employment
Road Construction – Dust	Construction Employment
Paved Road Travel – Freeways	VMT (freeway)
Paved Road Travel (Unspecified)	No Growth
Paved Road Travel-Major	VMT (major)
Paved Road Travel-Collector	VMT (other)
Paved Road Travel-Local	VMT (other)
Unpaved Road Travel -City and County Roads	No Growth
Unpaved Road Travel - US Forest and Park Roads	No Growth
Unpaved Road Travel -BLM Roads	No Growth

TABLE I-2-6 (CONCLUDED)
AREA SOURCES GROWTH SURROGATE BY SOURCE CATEGORY

SOURCE DESCRIPTION	SURROGATE
Unpaved Road Travel -Farm Roads	CARB Growth Data
Unpaved Roads (Unspecified)	No Growth
Ag Land (Non-Pasture) - Wind Dust	CARB Growth Data
Ag Land (Pasture) - Wind Dust	CARB Growth Data
Unpaved Roads - Wind Dust	No Growth
Fires	No Growth
Ag Burning – Pruning	CARB Growth Data
Agricultural Burning - Field Crops	CARB Growth Data
Range Improvement	Agriculture Output
Forest Management	Forest Management Services Data**
Wildland Fire Use (WFU)	CARB Growth Data
Weed Abatement	No Growth
Waste Burning (Unspecified)	CARB Growth Data
Cooking	Total Employment
Domestic Activity – Ammonia	Population

* These projections by SCG incorporate the energy efficiency programs/standards.¹⁷

** FRAP provided burn perimeters and ignition dates which is used in FOOEM model to estimate prescribed burning emissions; future year estimates are based on a 10-year average, held flat in the forecast.

Future Emission Trends and Agency Responsibilities

Even- and odd-numbered figures from Figures I-2-4 through I-2-11 present the relative contributions by source categories (i.e., point, area, on-road, and off-road) and the agency with primary authority to regulate emissions from the source category, respectively, for the years 2025, 2028, 2030 and 2031. These figures present total annual average emission levels for VOC, NO_x, NH₃, SO_x, and PM_{2.5}.

Odd-numbered figures from Figure I-2-5 to Figure I-2-11 show the emissions coming from sources under the primary regulatory purview of each of the three agencies – U.S. EPA, CARB, and South Coast AQMD – for all the milestone years. South Coast AQMD primarily oversees stationary sources via permitting, while CARB is responsible for selected area sources such as consumer products and pesticide/fertilizer and on-road and off-road mobile sources. Among off-road mobile sources, locomotive, OGVs, aircraft, selected heavy-duty trucks such as out-of-state, international registration, and interstate trucks are subject to federal and international regulations. Preempted off-road equipment with horsepower less than 175 are federally regulated as well.

NO_x emissions are one of the important precursors for ozone and PM_{2.5} formation, and majority of NO_x emissions fall under the authority of CARB and U.S. EPA. In 2030, 77 percent of the NO_x emissions fall under U.S. EPA and CARB control. Conversely, most SO_x, NH₃, and PM_{2.5} emissions are from sources under South Coast AQMD authority. Given the relationship between a growing population and economic activity, emissions regulations, and air pollution, the projections discussed in this chapter suggest that meeting the district's ozone and PM_{2.5} attainment obligations will require collaboration and efforts from all three agencies.

VOC Emissions: 364 tons/day

NOx Emissions: 239 tons/day

SOx Emissions: 15 tons/day

NH3 Emissions: 78 tons/day

PM2.5 Emissions: 54 tons/day

FIGURE I-2-11
2031 EMISSION INVENTORY AGENCY RESPONSIBILITY
(Annual Average)

Figures I-2-12 through I-2-16 illustrate the emission trends by pollutant (NO_x, VOC, SO_x, PM_{2.5}, and NH₃) for the same milestone years in the Draft 2024 PM_{2.5} plan: 2018, 2023, 2025, 2028, 2030, and 2031. Starting with Figure I-2-12 and Figure I-2-13, significant reductions in NO_x and VOC emissions are evident, particularly for the mobile source categories. As seen in Figures I-2-14 and I-2-15, PM_{2.5} and SO_x emissions experience little to no change from 2018 to 2031. NH₃ emissions are expected to increase through 2031 as shown in Figure I-2-16.

NO_x Emissions

Figure I-2-12 illustrates the NO_x emissions trend by major source category. Mobile sources are the major contributor to total NO_x emissions in the base year and future year inventories. NO_x emissions are projected to decrease in all major source categories with on-road mobile, off-road mobile, point, and area sources drop by 135, 24, 7, and 6 tons per day, respectively, between 2018 and 2031. Reductions in NO_x emissions primarily come from recently implemented regulations from CARB, such as Truck and Bus regulations, Advanced Clean Cars, Heavy Duty Low NO_x Omnibus,¹⁸ and Heavy-Duty Inspection and Maintenance¹⁹ regulations. These regulations result in corresponding declines in on-road NO_x emissions by 75 percent, respectively between 2018 and 2031, amidst overall respective reductions of 45 percent. Most of the anticipated on-road NO_x emission reductions are expected between 2018 and 2023, when Truck and Bus regulations are expected to take effect. On the other hand, beyond 2025, reductions are expected from regulations such as Advanced Clean Cars, Heavy Duty Inspection and Maintenance, and NO_x omnibus regulations. Off-road sources show a slight increase from 2025 to 2031 driven by an increase in aircraft emissions (from 19.6 to 25.7 tons per day) and OGV emissions (from 28.4 to 30.3 tons per day). Point and area sources decline by 30 and 15 percent, respectively from 2018 to 2031 due to regulation implementation from South Coast AQMD stationary sources rules such as R1109.1 for NO_x reduction from refinery and R1111 for NO_x reduction from residential natural gas heating furnaces.

FIGURE I-2-12
NOX EMISSION TREND BY SOURCE CATEGORY – ANNUAL AVERAGE

VOC Emissions

As shown in Figure I-2-13, area sources are major contributors to base and future years' VOC emissions. VOC emissions from area sources increase over time from 198 to 203 tons per day between 2018 and 2023 and increase to 217 tons per day in 2031. Within area sources, the main source of VOC emissions is consumer products. In 2018, VOC emissions from consumer products accounted for 27% of the total VOC emissions baseline, and this is expected to increase to 35% by 2030. Following population growth, VOC emissions from consumer products are set to increase over time, from 107 tons per day in 2018 to 124 tons per day in 2031. Coatings and related processes are the second-largest contributor to VOC emissions among area sources. Emissions from on-road mobile sources are set to decrease over time, with the largest decreases occurring prior to 2025, from 93 tons per day in 2018 to 65 tons per day in 2023. On-road emissions are expected to fall from 65 tons per day to 46 tons per day from 2023 to 2031. Off-road emissions show a similar trend dropping from 89 to 82 tons per day between 2018 and 2023; the rate of reduction is much more modest over the years between 2023 and 2031 (82 down to 56 tons per day) compared to the sharp reduction from base year 2018 to 2023. The amount of reduction from 2018 to 2031 for VOC emissions from on-road and off-road sources is expected to be 47 tons per day (50 percent) and 33 tons per day (37 percent), respectively; total VOC emissions reduction is 60 tons per day (15 percent). Because of increased activity due to demographic and economic growth, both point and area sources are expected to increase from 21 and 198 tons per day in 2018 to 22 and 217 tons per day in 2031, respectively. The increase of consumer products-related VOC emissions contribute 85 percent of the increase from point and area VOC emissions from 2018 to 2031.

FIGURE I-2-13
VOC EMISSION TREND BY SOURCE CATEGORY – ANNUAL AVERAGE

SOx Emissions

Figure I-2-14 illustrates the SOx emissions trend. Total SOx emissions show a slight increase from 2018 to 2031 due to marginal growth in point and off-road categories. Among off-road sources, OGVs are the primary source of SOx emissions which are expected to grow in future due to the increased ports activities. SOx emissions from on-road mobile sources are expected to slightly decrease from 2018 to 2023 and plateau beyond 2023; area sources plateau for all years (2018 through 2031). The overall 3 percent increase for total SOx emissions from 2018 to 2031 is mainly driven by the increase of aircraft and OGVs in the future.

FIGURE I-2-14
SOX EMISSION TREND BY SOURCE CATEGORY – ANNUAL AVERAGE

PM2.5 Emissions

Figure I-2-15 shows the PM2.5 emissions trend. Area sources, including entrained road dust, are projected to remain the largest contributor to PM2.5 emissions. Point and area sources are projected to increase from 2018 to 2031 due to increased activity driven by growth, resulting in higher emissions from commercial cooking, paved road dust, wood and paper production, as well as construction and demolition. The increase in vehicle miles traveled is the main cause of the increasing trend in paved road dust, while PM2.5 emissions from on-road mobile tail pipe emissions decrease due to the fleet turnover to cleaner vehicles. Off-road emissions slightly drop from 5.2 to 3.7 tons per day between 2018 and 2031. Overall, PM2.5 emissions are projected to decline by 4 percent from 2018 (56 tons per day) to 2031 (54 tons per day).

FIGURE I-2-15
PM2.5 EMISSION TREND BY SOURCE CATEGORY – ANNUAL AVERAGE

NH3 Emissions

Figure I-2-16 shows the NH3 emissions trend. Area sources are the largest contributor to NH3 emissions. Among area sources, emissions from human and pet perspiration are the largest source of NH3. Because this source is uncontrolled, emissions from this source are expected to increase over time as population increases. Another large contributor to NH3 is vehicle emissions. NH3 emissions from gasoline vehicles are a byproduct of the catalytic conversion of NOx in the three-way catalysts, whereas NH3 emissions from diesel vehicles are caused by the ammonia slip from SCR systems used in heavy-duty diesel vehicles. Because VMT in gasoline and diesel vehicles are expected to increase, NH3 emissions from vehicles is also projected to increase. Other NH3 sources in the basin include emissions from manufacturing, which are expected to remain relatively constant, and emissions from farming, which are projected to decline over time. Overall, NH3 emissions in the basin is projected to increase 7 percent from 75 tons per day in 2018 to 80 tons per day in 2031. NH3 emissions from human and pet perspiration alone contribute 44 percent of the total NH3 emission increase from 2018 to 2031.

FIGURE I-2-16
NH3 EMISSION TREND BY SOURCE CATEGORY – ANNUAL AVERAGE

Condensable and Filterable PM_{2.5} Emissions

Per PM_{2.5} NAAQS final implementation rule,²⁰ the SIP emissions inventory is required to separately identify condensable and filterable portions of PM_{2.5} within primary PM_{2.5} emissions. Primary PM emissions consist of condensable and filterable portions. Condensable PM is the material that is in vapor phase in stack conditions. The U.S. EPA's Air Emissions Reporting Requirements (AERR) requires states to report annual emissions of filterable and condensable components of PM_{2.5} and PM₁₀, "as applicable," for large sources for every inventory year and for all sources every third inventory year, beginning with 2011.²¹ Subsequent emissions inventory guidance²² from the U.S. EPA clarifies the meaning of the phrase "as applicable" by providing a list of source types "for which condensable PM is expected by the AERR." Filterable PM comprises "particles that are directly emitted by a source as a solid or liquid [aerosol] at stack or release conditions." Primary PM_{2.5} is the sum of condensable and filterable PM_{2.5} emissions. Category specific conversion factors

²⁰ 40 CFR 51.1008(a)(1)(iv).

²¹ 40 CFR §51.15(a)(1) and §51.30(b)(1).

²² USEPA. 2017. Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations. Available at: https://www.epa.gov/sites/production/files/2017-7/documents/ei_guidance_may_2017_final_rev.pdf.

developed by CARB and used in the Imperial County 2018 SIP²³ were applied in the current analysis to estimate condensable PM and then filterable PM was calculated by subtracting the condensable from the total PM2.5 primary emissions. The baseline 2018, future attainment year 2030, and the RFP milestone years 2023, 2025, 2028, and 2031 are included in the analysis. Figure I-2-15 shows the annual average emissions of primary (or direct), condensable, and filterable PM2.5 emissions for those years.

As shown in Figure I-2-19, total primary PM2.5 emissions increase between the base and future years, rising from 45.2 tpd in 2018 to 46.6 tpd in 2030. This increase in total primary PM2.5 is due to both condensable and filterable portions, which experience respective increases of 0.8 and 0.6 tpd between 2018 and 2031. The condensable portion shows a sharper increase than the filterable portion in the initial interim years from 2018 through 2023, with a 0.4 tpd increase versus little to no change. These increases can be attributed to the growth in population and economic activities in the Basin.

Table I-2-17 presents the top five source categories for condensable PM2.5 in 2018 and future milestone years. Most condensable PM2.5 is emitted from cooking, which accounts for 75.1% and 76.8% of the total condensable PM2.5 in 2018 and 2030, respectively. The sum of the top five condensable PM2.5 categories represents 95.7% and 95.9% of the total condensable PM2.5 both in 2018 and 2030, respectively. Table I-2-18 shows the top five categories for filterable PM2.5. Paved road dust is the greatest source of filterable PM2.5. The top five filterable PM2.5 emissions categories account for approximately 70.7% (2018) and 72.9% (2030) of the total filterable PM2.5 emissions. This points to a marginally higher contribution of the top five filterable categories to total filterable PM2.5 emissions in future years.

List of Category Specific Conversion Factors (Developed by CARB and Used in the Imperial County 2018 SIP) to Estimate Condensable PM2.5 from Primary PM2.5 as well as detailed emissions by major source category for condensable and filterable PM2.5 are included in Appendix I Attachment E of this Plan.

Uncertainty in the Inventory

An effective PM Plan relies on a robust emission inventory. Over the years, significant improvements have been made to quantify emission sources for which control measures are developed. Increased use of continuous monitoring and source tests has contributed to the improvement in point source inventories. Technical assistance to facilities and auditing of reported emissions by South Coast AQMD also have improved the accuracy of the emissions inventory. CARB inventory staff collaborates with the South Coast AQMD to ensure the accuracy of these data. The locations of point sources, including stacks, are checked for validity. Area source inventories that rely on average emission factors and regional activities have inherent uncertainty. Area source emissions estimates are developed by both CARB and South Coast AQMD staff, and the methodologies are reviewed by both agencies before their inclusion in the emissions inventory. Industry-specific surveys and source-specific studies during rule development have provided much-needed refinement to the emissions estimates. Many sectors in area sources were revised extensively as well based on the best available emission factors and activity data. As described earlier, many improvements are included in the on-road mobile source model EMFAC2021 which estimates emissions from trucks, automobiles, and buses. Improvements and updates are included in the off-road models for locomotives, OGVs, commercial harbor craft, pleasure craft and off-road recreational vehicles, cargo handling equipment, and farm equipment. Mobile categories are verified with CARB mobile source staff for consistency with the on-road and off-road emission models.

CARB maintains and assembles base year emissions in the California Emission Inventory Development and Reporting System (CEIDARS), which is designed with automatic system checks to prevent errors, such as double counting of emission sources. At the final stage, California Emissions Projection Analysis Model (CEPAM), a tool designed and maintained by CARB to model emissions inventory for the 2022 State SIP Strategy is thoroughly reviewed by CARB staff as well as South Coast AQMD staff to validate the accuracy of growth and control application, and the output emissions are compared against prior approved versions of CEPAM to identify data anomalies.

Overall, the ~~Draft~~ PM2.5 Plan inventory is based on the most current information and estimation methodologies, resulting in the most accurate inventory available. However, there are still areas that could be improved if better data were available. Technology changes and improvements in the area of electric, hybrid, flexible fuel, and fuel cell vehicles, or the change in future gasoline prices, all add uncertainty to the future on-road emissions inventory.

Relative to future growth, there are many challenges involved with making accurate projections, such as where vehicle trips will occur, the distribution between various modes of transportation (such as trucks and trains), as well as estimates for population growth and changes to the number and type of jobs. Forecasts are made with the best information available; nevertheless, they contribute to the overall uncertainty in emission projections. Fortunately, AQMP updates are generally performed every three to five years; thereby allowing for frequent improvements and adjustments to the inventories.

Controlled Emission Inventories

This section describes the methodology used to estimate the controlled and remaining emissions after the proposed control measures in the Draft PM2.5 Plan are implemented for the year 2030. Emission reductions are derived by applying the control efficiency of a control measure to the projected baseline inventories.

The methodology used in this Draft PM2.5 Plan to calculate emission reductions from the implementation of the proposed control measures and remaining emissions is the same methodology used in the 2022 AQMP.²⁴ The in-house algorithm calculates remaining emissions as well as reductions for each control measure using the control factors specified at the Emission Inventory Codes (EIC) level for a given year and pollutant. It is not unusual to have more than one control factors targeting the same EIC when multiple rules exist. To avoid double counting of reductions, the composite control factor is used by multiplying the individual control factors for the same EIC. Details of the steps taken in the calculation are discussed in the “Emission Reduction Calculations” section of this document.

Emission Reductions from the Proposed Control Measures

To assess emission reduction potential and remaining emissions from proposed control measures, a control factor profile needs to be developed identifying the source category targeted by each measure, its control efficiency, and the implementation schedule.

Control Efficiency/Control Factor

One factor that determines the effectiveness of a control measure is its control efficiency (CE), expressed in percentage. Control efficiency is dependent on the specific control technologies proposed, and each control measure may have one or more technology options available. If there is only one feasible control technology in a control measure, its control efficiency is primarily based on an engineering evaluation of the proposed technology. However, if several control technologies are available to control an emission source, the average control efficiency is used. If multiple control technologies are proposed to reduce emissions from various steps of an operation, a weighted average control efficiency is developed to represent an overall control of the emission sources. Once the control efficiency of a control measure is determined, it is used to estimate emission reductions of the proposed measure. Control efficiencies for the proposed control measures are identified and discussed in detail in Appendix IV of the Draft PM2.5 Plan.

The control factor (CF) is used to estimate remaining emissions once a proposed control measure is implemented. A control factor equal to 0 indicates complete emission control or 100 percent efficiency. A control factor equal to 1 indicates no emission control or emissions remain unchanged. A high control factor value indicates a low control efficiency. As the control efficiency goes up, the control factor value goes down. The equation to calculate a control factor follows:

²⁴ 2022 AQMP Appendix III: Base and Future Year Emission Inventory <http://www.aqmd.gov/docs/default-source/clean-air-plans/air-quality-management-plans/2022-air-quality-management-plan/final-2022-aqmp/appendix-iii.pdf?sfvrsn=6>

$$CF = 1 - (CE/100)$$

The remaining emissions can be calculated as:

$$REM = BE \times CF$$

Where REM is Remaining Emissions, and BE is Baseline Emissions.

To assess the influence of control measures on future PM2.5 levels, control factors for 2030 were developed. The control factor profile for each measure is developed considering the following factors:

- proposed adoption date;
- implementation lead time; and
- phase-in period, if any.

The adoption date as proposed in the ~~Draft~~ PM2.5 Plan is the date South Coast AQMD or another agency is expected to adopt the control measure as a rule. The implementation lead time reflects the time allowed for the emission sources to install controls. When a rule is implemented, it is not unusual that it may have multiple interim implementation dates prior to full implementation. This is because the requirements in a rule may require two or three phases to include such as technology-forcing regulation to reach the final emission target. Sometime, a particular rule may regulate such a large population of equipment that it is impractical to implement it all at once, then, it becomes administratively necessary break down the implementation into different phases. In either case, a control profile would indicate an initial implementation date and an ending implementation date. The adoption and implementation schedule of the proposed control measures is presented in Chapter 4 of the ~~Draft~~ PM2.5 Plan.

Impact Factors

Each proposed control measure describes specific emission sources subject to potential controls. Based on the description of these sources, corresponding sources as tracked in the emission inventory are identified. In general, emission sources are grouped by major source category, which can be further subcategorized into point sources denoted by Source Classification Codes (SCC) and area sources denoted by Category Emission Source (CES) Codes. To track emission reductions more accurately, the control factors at the SCC/CES level become necessary.

An SCC, an 8-digit EPA code, is used to identify emissions from a point source at the equipment level. A CES, a 5-digit CARB code, is used to describe an area source for which emissions are distributed across the region with no specific locations.

For some measures, the controls apply not only to the type of equipment but also to the industries engaged in a particular activity. In those cases, control factors will be developed by pairing SCCs with Standard Industrial Classification (SIC) Codes to clearly and specifically point out the emission sources in the inventory that the measure is designed to reduce. Such SCC/SIC pairs significantly enhance the ability to quantify emissions closely following the intent of a proposed control measure.

There are instances where an SCC or CES category is not fully impacted by a control measure. As a result, an impact factor (IF) is developed as a weighing factor for such an adjustment. The following equation illustrates how the impact factor (IF) is included in the CF calculation.

$$CF = 1 - ((CE / 100) \times IF)$$

Impact factors will accurately track the measure's baseline emissions and calculate more accurate reductions from the proposed control measures.

Emission reductions for the attainment year 2030 for South Coast Air Basin are estimated from the control measures provided in Chapter 4 and Appendix IV of this Draft PM2.5 Plan.

Emission Reduction Calculations

An in-house algorithm (in MATLAB programming language) is developed to calculate the emission reductions from controlled emission scenarios. A brief description of the steps taken in the algorithm is as follows:

- I. Compile baseline emissions by EIC:
Compile the annual baseline emissions (BE) by EIC for each pollutant and year. Attachment A in Appendix I present the annual average emission summary tables for the South Coast Air Basin by major source categories.

Baseline Emissions by year, pollutant and EIC: $BE_{year,pol,EIC}$

- II. Compile composite control factors for all measures by EIC:
The control factors by pollutant and year are provided by South Coast AQMD rule writers or CARB staff for each proposed control measure. The composite control factors by EIC and pollutant are obtained by multiplying all control factors applied to the same EIC to reflect the overall reduction resulting from the application of all control and incentive measures to the baseline emissions.

Example: Assume there are 2 control measures applying to 3 EIC codes

Control factors for measure 1 applies to EIC1 and EIC2:

$$CF1_{year,pol,EIC1} \text{ and } CF1_{year,pol,EIC2}$$

Control factors for measure 2 applies to EIC1 and EIC3:

$$CF2_{year,pol,EIC1} \text{ and } CF2_{year,pol,EIC3}$$

Composite control factors for the 3 EIC are:

$$CCF_{year,pol,EIC1} = CF1_{year,pol,EIC1} \times CF2_{year,pol,EIC1}$$

$$CCF_{year,pol,EIC2} = CF1_{year,pol,EIC2}$$

$$CCF_{year,pol,EIC3} = CF2_{year,pol,EIC3}$$

III. Calculate remaining Emissions:

Calculate the remaining emissions after multiplying the composite control factors by baseline emissions, by EIC, pollutant, and year. The result is the remaining emissions after applying all defined measures and South Coast AQMD incentive programs for mobile and stationary sources.

Example: Apply the control factors of measures 1 and 2 to baseline emissions of EIC1, EIC2 and EIC3 to calculate controlled emissions (CE)

$$CE_{year,pol,EIC1} = CCF_{year,pol,EIC1} \times BE_{year,pol,EIC1}$$

$$CE_{year,pol,EIC2} = CCF_{year,pol,EIC2} \times BE_{year,pol,EIC2}$$

$$CE_{year,pol,EIC3} = CCF_{year,pol,EIC3} \times BE_{year,pol,EIC3}$$

IV. Add back set-aside account emissions to remaining basin total for the controlled emissions scenario.

The result of emission reductions from the proposed control measures for 2025 and 2030 are presented in Appendix II of the ~~Draft~~ PM2.5 Plan.

CARB Emission Data Reports System

As mentioned in Chapter 1 of this Appendix, the entire emission inventories are compiled and maintained by CARB in its statewide emission related information databases, namely the California Emission Inventory Development and Reporting System (CEIDARS) and the California Emission Forecasting and Planning Inventory System (CEFIS).

In both systems, emissions are tracked by EIC codes. The EIC code is a 14-digit number arranged into four fields: major category, source category, material description, and emission sub-category. For example, EIC 210-200-3300-0000 is for dry cleaning using perchloroethylene. 210 indicates that this source is under the laundering group. 200 means the source category is dry cleaning. 3300 refers to the material perchloroethylene. 0000 implies there is no sub-category for this particular source. EIC codes separate emission sources into four major divisions: stationary, area, non-anthropogenic, and mobile source. This coding system allows flexibility in how sources are selected, sorted, and grouped to fit users' needs. EIC codes link area sources and point sources together to allow a computer program to automatically reconcile point and area source emissions. In the ~~Draft~~ PM2.5 Plan, all the emission summary reports are based on CARB's EIC codes. Because only anthropogenic sources are included in this document, all summary reports in the appendices include three major divisions: stationary, area, and mobile sources.

The California Emissions Projection Analysis Model (CEPAM)²⁵ was created to support SIP development, air quality modeling efforts, and SIP progress tracking. CEPAM starts with a base year, which is pulled from CEIDARS, and forecasts emissions for point and area sources using the most current growth and control data available at the time of the development of the model version. For mobile sources, CEPAM integrates the

²⁵ <https://ww2.arb.ca.gov/criteria-pollutant-emission-inventory-data#:~:text=California%20Emissions%20Projection%20Analysis%20Model&text=CEPAM%20starts%20with%20a%20base,development%20of%20the%20model%20version.>

emission estimates from EMFAC and OFFROAD²⁶ mobile source emission models to provide a comprehensive anthropogenic emission inventory. CEPAM2022 projected from 2018 using control and growth factors employed for this PM plan will be released and hosted on CARB's website for public review.

Regional Modeling

Relative Response Factors and Future Year Design Values

Modeling Results

Uncertainties Associated with the Technical Analysis

Document Organization

Introduction

Air quality modeling to demonstrate future attainment of air quality standards is an integral part of the planning process to achieve clean air. Modeling provides the means to relate emission reductions from pollution sources to the resulting air quality improvements. The attainment demonstrations provided in this ~~Draft~~ PM_{2.5} Plan reflect updated emissions estimates, new technical information, enhanced air quality modeling techniques, updated attainment demonstration methodology, and the control strategies provided in Chapter 4.

This ~~Draft~~ PM_{2.5} Plan aims to develop a control strategy and corresponding attainment demonstration that: 1) ensures that the 2012 annual PM_{2.5} National Ambient Air Quality Standard (NAAQS) is met by the established deadline in the federal Clean Air Act (CAA) and 2) achieves an expeditious rate of progress towards attaining the air quality standard.

The South Coast Air Basin is classified as an “serious” nonattainment area for the 2012 annual PM_{2.5} NAAQS with an attainment year of 2025. This plan seeks an extension of the attainment to 2030 and included control strategy and modeling demonstration to attain in 2030. The modeling base year is 2018 and was used to derive meteorological inputs; it also served as an anchor year to project future emissions and was used in the attainment demonstration.

Modeling Methodology

Design Values

U.S. EPA guidance recommends the use of multiple year averages of design values, where appropriate, to dampen the effects of single year anomalies to the air quality trend due to factors such as adverse or favorable meteorology or radical changes in the local emissions profile. The Basin PM_{2.5} design value trend is presented in Chapter 5 of the ~~Draft~~ PM_{2.5} Plan, Figure 5-1. The trend in the Basin Annual PM_{2.5} design values from 2001 through 2022 reveals substantial reductions in concentrations over this timeframe. The year 2020 was particularly anomalous for a variety of reasons such as recorded-setting wildfires and pandemic-era emissions. The five-year period, 2016-2020 was used in the current modeling attainment demonstration. However, due to the anomaly of year 2020 related with COVID-19 pandemic and record-setting wildfires, a five-year weighted design value recommended by U.S. EPA was modified to exclude the impact 2020 measurements. Chapter 5 of the ~~Draft~~ PM_{2.5} Plan discusses the detail of the 5-year weighted design value calculations.

Model Selection

The attainment demonstration was developed using the U.S. EPA Community Multiscale Air Quality (CMAQ) (version 5.3.3) modeling platform with Statewide Air Pollution Research Center (SAPRC) 07 chemistry and aerosol mechanism of aero6, and the Weather Research and Forecasting Model (WRF)

(version 4.4.2) meteorological fields. Comprehensive descriptions of the CMAQ modeling system are provided by U.S. EPA.¹ Additional descriptions of the SAPRC07 chemistry module and aerosol mechanism of aero6 are provided are available online.² Documentation of the National Center for Atmospheric Research (NCAR) WRF model is available from the University Corporation for Atmospheric Research (UCAR).³

Regional Modeling

The CMAQ air quality modeling platform with SAPRC07 chemistry and WRF meteorology were employed as the primary tool used to demonstrate future year attainment of the PM_{2.5} standard. Simulations are conducted from January 1st to December 31th. Daily average values of PM_{2.5} concentrations were Predicted.

As in the 2022 AQMP, simulations were conducted using a Lambert Conformal grid projection where the western boundary of the domain is at 084 UTM, over 100 miles west of the ports of Los Angeles and Long Beach. The eastern boundary extends beyond the Colorado River, while the northern and southern boundaries of the domain extend to the southern edge of the San Joaquin Valley and the Northern portions of Mexico (3543 UTM). The grid size is 4 x 4 kilometers with 30 vertical layers. Figure II-1-1 depicts the CMAQ modeling domain which includes a grid of 156 cells from west to east and 102 cells from south to north.

² <https://intra.engr.ucr.edu/~carter/SAPRC/>

³ <https://www.mmm.ucar.edu/models/wrf>

FIGURE II-1-1

CMAQ Regional Modeling Domain for the Draft PM_{2.5} Plan

WRF was updated to the most recent version (version 4.4.2) available at the time of this protocol preparation and was evaluated with a set of observation data. The WRF simulations were initialized from National Centers for Environmental Prediction (NCEP) North American Regional reanalysis (NARR) Reanalysis data and run for 4-day increments with the option for four-dimensional data assimilation (FDDA). The atmospheric chemistry package used in the CMAQ simulations relied on SAPRC07 gas phase chemistry with version “c” toluene updates with the AERO6 aerosol mechanism, the Euler Backward Iterative solver, the Yamo horizontal advection scheme, the WRF vertical advection scheme, the multiscale CMAQ horizontal diffusion scheme, the ACM2 vertical diffusion scheme, in-line photolysis calculations, and clean homogeneous initial values.

Relative Response Factors and Future Year Design Values

To bridge the gap between air quality model output evaluation and applicability to the health-based air quality standards, EPA guidance⁴ has proposed the use of relative response factors (RRF). South Coast AQMD developed a tool to calculate the RRF and did not rely on EPA’s MATS/SMAT software. The RRF is simply a ratio of future year predicted air quality with the control strategy fully implemented to the simulated air quality in the base year (U.S. EPA, 2018). For PM_{2.5} simulations, PM_{2.5} component-specific

⁴ U.S. EPA (2018) Modeling Guidance for Demonstrating Air Quality Goals for Ozone, PM_{2.5}, and Regional Haze.

relative response factors (RRF) should be calculated for each quarter. The guidance requires that quarterly mean concentrations for each component to be determined among 9 grid cells around a monitoring station if model grid resolution is equal or less than 12km and that the specific grid location be preserved in the future year modeling scenario when calculating. The ratio of base to future year quarterly mean concentrations for each component is the RRF for that component.

The future year design value is estimated by multiplying the non-dimensional RRF to the measured base year design value. Thus, the simulated improvement in air quality, based on multiple meteorological episodes, is translated to a simple metric that directly determines compliance of the standard. Equations II-1-1 and II-1-2 summarize the calculation.

Equation II-1-1:

$$\text{RRF} = \frac{\text{Future Year Model Prediction}}{\text{Base Year Model Prediction}}$$

Equation II-1-2:

$$\text{Future Design Value} = \text{RRF} \times \text{Base Design Value}$$

The modeling analyses described above use the RRF method to project future design values. A future design value less than or equal to the standard constitutes attainment. The RRF approach aims to minimize the effects of biases in the model simulations, thus providing more accurate projections of future air quality.

Modeling Results

Air quality modeling simulations are conducted to quantify the air quality improvements resulting from the measures proposed in the ~~Draft~~ PM2.5 Plan, and to demonstrate that future PM2.5 concentrations will meet the air quality standards. Modeling results show that the measures proposed in this ~~Draft~~ PM2.5 Plan will be able to bring PM2.5 concentrations down and that all areas in the Basin will be in attainment of the 2012 annual PM2.5 standard by 2030.

Uncertainties Associated with the Technical Analysis

As with any attainment plan, there are uncertainties associated with the technical analysis. Uncertainties are inherent to many of the inputs used in the emissions, meteorological and air quality models. Uncertainty in emission projections stem from the uncertainties associated with the demographic and socioeconomic factors, the emission factors and the spatial distribution surrogates used in the development of emissions inventories. Modeling tools also contribute to the uncertainty as all models can only be a limited representation of the real world. Also, uncertainty in the measurements add to the

uncertainty when model performance is assessed. And finally, uncertainty in future climate may also impact our understanding and ability to determine the necessary emission controls to attain the standards. While completely eliminating uncertainties is an impossible task, there are a number of features and practices built into the air quality planning process that manage and control such uncertainties and preserve the integrity of an air quality management plan. These measures include the constant revision of modeling tools and the design of contingency measures that could be enacted in the event that the measures in the Draft PM2.5 Plan do not result in the projected air quality improvements.

Document Organization

This document provides the federal attainment demonstration for PM2.5. Chapter 2 provides the modeling protocol which summarizes the key elements that have been revised relative to the 2022 AQMP modeling protocol. Chapter 3 provides a discussion of the meteorological modeling including a comprehensive model performance evaluation. Chapter 4 provides a brief summary of the modeling emissions, boundary conditions and initial conditions. Chapter 5 discusses the annual PM2.5 attainment demonstration for the 2030 attainment year. The PM2.5 analysis includes discussions of base-year modeling performance, and projections of future year PM2.5 concentrations for baseline emissions. Table II-1-2 lists the Attachments to this document.

MODELING PROTOCOL

Background

Attainment Demonstration

Numerical Models

Emissions Processing

Biogenic Emissions

Computational Resources

Background

One of the basic requirements of a modeling attainment demonstration is the development of a comprehensive modeling protocol that defines the scope of the regional modeling analyses. This includes the attainment demonstration methodology, meteorological and chemical transport platforms, gridded and speciated emission inventories, and geographical characteristics of the modeling domains. The protocol also defines the methodology to assess model performance and the selection of the simulation periods. The 2016 AQMP provided a comprehensive discussion of the modeling protocol used for the development of the PM_{2.5} and ozone attainment demonstrations. The 2016 AQMP Modeling Protocol served as the prototype of the ~~Draft 2024~~ PM_{2.5} Plan modeling protocol. This ~~Draft 2024~~ PM_{2.5} Plan demonstrates attainment of the 2012 annual PM_{2.5} standard with 2018 as the base year and 2030 as the attainment year. Future attainment years (See Table II-2-1) are identified based on nonattainment designation, pollutant standards, and geographical area.

TABLE II-2-1
UPCOMING ATTAINMENT YEARS FOR THE 2012 ANNUAL PM_{2.5} NAAQS FOR THE SOUTH COAST AIR BASIN

Attainment Year	Remarks
2018	Base Year for Modeling and Emissions Projection
2025	2012 PM _{2.5} Serious Area Attainment Due
2030	2012 PM _{2.5} Serious Area with 5 -year Extension

Attainment Demonstration

The annual PM_{2.5} attainment demonstration was performed based on the U.S. EPA guidance document, “Modeling Guidance for Demonstrating Air Quality Goals for Ozone, PM_{2.5}, and Regional Haze”, issued on November 29, 2018 (U.S. EPA, 2018). To predict the future annual PM_{2.5} design values, PM_{2.5} component-specific relative response factors (RRF) should be calculated for each quarter. The guidance requires that quarterly mean concentrations for each component to be determined among 9 grid cells around a monitoring station if model grid resolution is equal or less than 12km and that the specific grid location be preserved in the future year modeling scenario when calculating. The ratio of base to future year quarterly mean concentrations for each component is the RRF for that component.

Numerical Models

Table II-2-2 provides a side-by-side comparison of the 2016, 2022 AQMP and the current ~~Draft 2024~~ PM_{2.5} Plan modeling protocols. In general, changes have occurred in the following categories: emissions inventories, future-year simulations, the level of the non-attainment designation and the attainment demonstration methodology. As such, these changes are expected to occur with each subsequent modeling update. Table II-2-3 highlights the main differences in CMAQ setup since the 2022 AQMP.

The Weather Research and Forecast (WRF) model remains the primary tool for meteorological modeling. WRF was updated with the most recent version (version 4.4.2) available and was evaluated with a set of observation data to ensure the accuracy and reliability of meteorological predictions. WRF simulations were conducted with three nested domains with grid resolutions of 36 km, 12 km and 4 km. The innermost domain spans 652 km by 460 km in the east–west and north–south directions, respectively, which includes the greater Los Angeles area, its surrounding mountains, and ocean waters off the coast of the South Coast Air Basin (Figure II-2-1). A Lambert conformal map projection was used with reference latitudes of 30° and 60° N and the center of the modeling domain positioned at 37° N and 120° 30' W. Details on the WRF model configuration are provided in Chapter 3 of Appendix II.

FIGURE II-2-1

Emissions Processing

Emissions inventories are often developed on an annual basis for large geographic areas and a process must be developed to allocate the emissions to a time-dependent grid for use in chemical transport modeling. Traditionally, emissions were allocated to the modeling grid using generic or average activity patterns and profiles. These approaches did not sufficiently reflect the real-world characteristics of emissions sources. Shortcomings of previous emissions allocation methods included an inability to account for traffic flows responding to changes in weather, vessels transiting outside of well-known shipping lanes, or aircraft following airport-specific landing and takeoff trajectories. For these reasons, new approaches were developed to spatially and temporally allocate emissions from on-road mobile sources, Ocean-Going Vessels (OGV), and aircraft. Each method used information from sensor or transponder-based datasets, which accurately reflected where and when emissions were occurring. Further details on the updated allocation methods are presented in Chapter 4 of Appendix II.

¹ Wildfires and prescribed burns were modeled using day-specific profiles for the model performance evaluation only. For the attainment demonstration, wildfire emissions were excluded, and prescribed burns were modeled using a generic profile.

Biogenic Emissions

Daily biogenic VOC emissions were calculated using the Model of Emissions of Gases and Aerosols from Nature version 3.0 (MEGAN3.0) using 2018 meteorology as input. MEGAN was executed in its default configuration, except for the normalized Leaf Area Index (LAIv) input. LAIv was developed by the California Air Resources Board using 2018 data from the Moderate Resolution Imaging Spectroradiometer (MODIS) on the National Aeronautical Space Administration's Terra and Aqua satellites. Because MODIS does not provide data in urban areas, LAIv in these areas was based on tree survey data from the US Forest Service. A detailed description of the biogenic inventory is provided in Chapter 4 of Appendix II.

Computational Resources

The main computation platform employs high performance nodes. New servers, compiled to enhance computational capability, were configured with Red-Hat Enterprise Linux 7 and 64-bit operating systems. Details of the computing resources are summarized in Table II-2-6.

Sensitivity Test of Planetary Boundary Layer Scheme

Summary

Overview

This chapter provides a description of the meteorological modeling that serves as the foundation of the ~~Draft 2024~~ PM2.5 plan modeling analysis. The Weather Research and Forecasting (WRF) model was used to generate meteorological fields for further modeling analysis. The model offers a variety of user options to cover atmospheric boundary layer parameterizations, turbulent diffusion, cumulus parameterizations, land surface-atmosphere interactions, which can be customized to specific geographical and climatological situations. South Coast AQMD staff performed extensive sensitivity tests and developments to improve WRF performance for the South Coast Air Basin, where prediction of complex meteorological structures associated with air quality episodes is particularly challenging due to the region's unique geography and climate. This chapter describes the numerical configuration, sensitivity test on key parameterizations, input database, and initial and boundary values used in the ~~Draft 2024~~ PM2.5 Plan modeling analysis.

Comparison of 2018 Observed Meteorology to 10-Year Average

Meteorological data from airport weather stations across the Basin and the Coachella Valley were used to assess differences between regional weather patterns observed in 2018 and average conditions from 10 years (2013-2022). The 15 weather stations used for this analysis were Los Angeles International Airport (LAX), Santa Monica Municipal Airport (SMO), Hawthorne Municipal Airport (HHR), Long Beach Airport (LGB), John Wayne Airport (SNA), Fullerton Municipal Airport (FUL), Chino Airport (CNO), Ontario International Airport (ONT), Riverside Municipal Airport (RAL), March Air Reserve Base (RIV), Palm Springs International Airport (PSP), Burbank Bob Hope Airport (BUR) and Van Nuys Airport (VNY). The location of the stations is shown in Figure II-3-1. Comparisons of 2018 and 2013-2022 daily total rain, daily average wind speed, relative humidity and temperature at the station of LAX are shown as examples in Figures II-3-2 through II-3-5. Comparisons for all other stations are included in Attachment 1 of Appendix II.

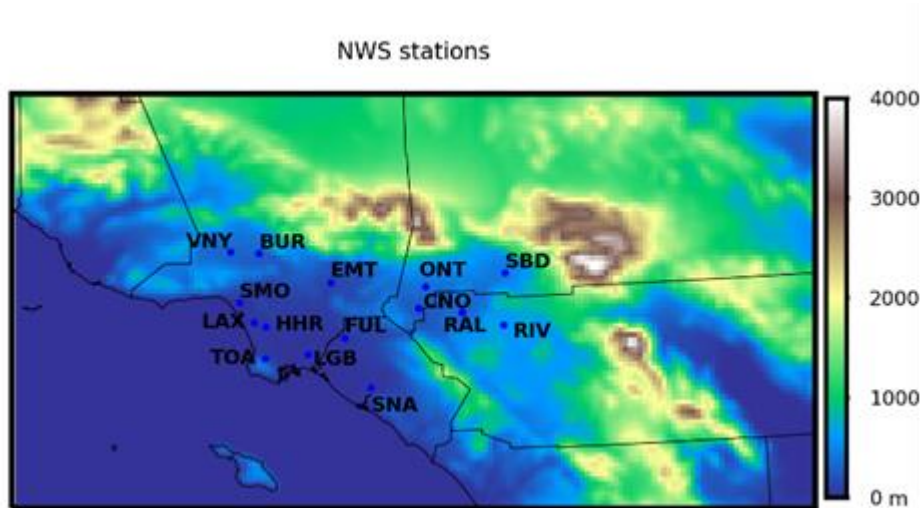

FIGURE II-3-1

15 NATIONAL WEATHER SERVICE (NWS) STATIONS AND TOPOGRAPHY IN THE BASIN

As shown in Figure II-3-2, the daily total rain at the station of LAX recorded higher precipitation for some years such as 2017, 2019 and 2021. Lower precipitation is observed during years such as 2013 and 2022. Typically, the first quarter and the 4th quarter of the year are the rain seasons. For example, the first quarter of 2017 and the last quarter of 2021 observed more than 2 inches daily total rain. There are more rain days with > 1 inch daily total rain in the year of 2019 from both first quarter and 4th quarter. On the other side, the year of 2013 is dry and observed the lowest rain amount comparing with other years. Regarding both precipitation days and rain amount, the year of 2018 observed values between the lower and the higher values among the 10 years precipitation record. Figure II-3-3, II-3-4, and II-3-5 are normalized histogram of daily average at station of LAX in 2018 and the 10-year (2013-2022) for wind speed, relative humidity, and temperature respectively. The higher value range for the above three variables in 2018 are in line with the counterparts from the 10 years observations. The histogram of 2018 didn't show much shifting to the higher or the lower values comparing with the 10 years normalized histogram. For example, the higher wind speed is in the 2.5 m/s - 4 m/s range for both 2018 and the 10 years observations. The higher relative humidity is in the 65% - 85% range for both 2018 and the 10 years observations.

Modeling Configuration

The WRF model is one of the most widely used meteorological models for both operational forecasting and research applications. WRF has been applied to a wide range of phenomena across geographic scales from tens of meters to thousands of kilometers, such as regional climate, monsoons, baroclinic waves, mesoscale fronts, hurricanes, deep convection, land-sea breezes, mountain-valley circulations, large eddy simulations, and fire events. The model is supported by the National Center for Atmospheric Research (NCAR) and actively developed by a worldwide user community. The WRF system contains two dynamical solvers, referred to as the ARW (Advanced Research WRF) core and the NMM (Nonhydrostatic Mesoscale Model) core. The ARW configuration was used for the Draft 2024 PM_{2.5} Plan modeling analysis. The ARW is primarily developed and maintained by the NCAR Mesoscale and Microscale Meteorology Laboratory.

The WRF model is a fully compressible and nonhydrostatic model (with a run-time hydrostatic option). For vertical coordinate, the model uses either a terrain-following (TF) or hybrid vertical coordinate (HVC). The grid staggering is the Arakawa C-grid¹ (Skamarock, W. C., 2019). It uses a time-split small step for acoustic and gravity-wave modes. The dynamics conserve scalar variables. The WRF is designed to be a flexible, state-of-the-art atmospheric simulation system that is portable and efficient on parallel computing platforms.

The WRF simulation domain designed for the Draft 2024 PM_{2.5} Plan encompasses the greater Los Angeles and suburban areas, its surrounding mountains, and ocean off the coast of the Basin, as shown in Figure II-3-6. WRF simulations were conducted with three nested domains at grid resolutions of 36 km, 12 km, and 4 km. The innermost domain has 163 by 115 grid points, which span 652km by 460km in east-west and north-south directions, respectively. Figure II-3-6 also shows the relative locations and sizes of the three nested grids. The innermost domain presented in Figure II-3-6, excluding three boundary columns and rows, served as the CMAQ (Community Multiscale Air Quality Model) chemical transport modeling domain.

The WRF simulation employed 30 layers vertically with the lowest computational layer at approximately 20 m above ground level (agl) and the top layer at 50 hPa. Four-Dimensional Data Assimilation (FDDA) was conducted using grid analysis data enhanced with available surface and vertical sounding data. Sea surface temperatures (SST) are a critical control on the land-sea breeze and up-slope/down-slope flow. SST data from the Global Data Assimilation Experiment (GODAE) were used to update the WRF modeling every 6 hours to better represent the sea surface temperature. The Yon-Sei University (YSU) scheme² (Hong and

FLOWCHART OF WRF SIMULATION FOR 2024 DRAFT PM_{2.5} PLAN

Model Performance Evaluation: Surface Level

The performance of the WRF simulations is summarized in Table II-3-2 for 4 quarters of 2018. All the results shown in Table II-3-2 are averaged values for the 15 airport weather stations. Overall, WRF simulations for 4 quarters provided representative meteorological fields that well characterized observed conditions in 2018. These fields were used directly in the CMAQ joint particulate simulations.

The performance of WRF simulations used as transport fields for CMAQ modeling is shown in Figure II-3-8 through Figure II-3-16. The model performance was evaluated for each month at airport stations in the model domain for January through December 2018. For simplicity, only one summer month (July) and one winter month (January) are shown in Figure II-3-8 through Figure II-3-16.

Three weather stations are carefully selected from near coastal areas (HHR, Hawthorne municipal Airport) through inland Orange County (FUL, Fullerton Municipal airport) to further east in San Bernardino County (CNO, Chino Airport) for surface level model performance evaluations. Diurnal variations of temperature,

humidity and surface wind were well represented by the WRF simulations. Temperature and wind speed predictions were more accurate in the summer season than the winter months (Figure II-3-8 – Figure II-3-13). The observed temperature gradient from the coastal station of HHR to the inland station of CNO was also well characterized by the WRF model. Median observed summer temperatures in 2018 were 296.6, 298.7, and 300.9 K at HHR, FUL and CNO, respectively. The WRF model showed similar median temperature for these stations. Temperature is one of the key factors for atmospheric photochemical reactions, and high temperature is favorable for ozone formation. For the stations of CNO, the WRF simulations showed slight underestimation of daily high temperatures during July 2018. At the station of FUL and HHR, the WRF simulation showed better performance in predicting daily high temperatures in the summer. During the winter, daily high temperature predictions were closer to observed values during the 2nd half of January 2018 at all three stations. While the model tended to overpredict the daily minimum temperatures during the 2nd half of January 2018 at CNO and FUL.

Both observational data and WRF simulations at all stations showed distinct diurnal variations in wind speed during the summer, with a strong sea breeze in the early afternoon. Mostly, stronger wind speed indicates less accumulation of air pollutants. Daily maximum wind speeds were relatively consistent throughout July 2018, with much more variability observed during January 2018 (e.g., range of daily maximum wind speeds from ~2-13 m/s during January at CNO from both measurements and simulations). The model performance in predicting the wind speed was significantly better for July 2018 compared to January 2018 at all stations; R values for model-observation correlations were 0.81, 0.70, and 0.78 in July 2018 at CNO, FUL, and HHR stations, respectively. It is noticed that the model underestimated daily maximum wind speeds at the HHR station during July 2018.

The WRF model predicted water vapor mixing ratio trends well at all stations. The WRF simulations yield water vapor mixing ratios comparable to observed values in both January and July. The model-observation correlation coefficients are 0.85, 0.87, and 0.89 in January 2018 and 0.72, 0.70, and 0.71 in July 2018 at CNO, FUL, and HHR stations, respectively.

Model Performance Evaluation: Diurnal Variations

Comparisons of simulated and measured monthly average diurnal temperature and water vapor mixing ratio variations at the Fullerton (FUL) station are shown in Figure II-3-17 and Figure II-3-18. Seasonal differences between summer and winter, as represented by July and January, respectively, and diurnal patterns were well reproduced in the WRF simulation. For example, daily temperatures in both observed and simulated diurnal profiles peaked around 14:00 local time during summer (~ 297 K) and winter (~ 290 K). Water vapor mixing ratios did not exhibit distinct diurnal variation in either observed or simulated data.

Model Performance Evaluation: Wind Rose

The measured and WRF simulated wind rose at each station for 1-year period of January – December 2018 are shown in Figure II-3-19 – Figure II-3-23. Consistent with the sections above, the wind rose at HHR (near coastal areas), FUL (inland Orange County) and CNO (further east in San Bernardino County) are presented. Another two stations: BUR (inland Los Angeles County) and ONT (San Bernardino County) are included as well to evaluate the model performance in further downwind areas. In general, the WRF simulations reproduce the dominant wind direction as the measurements at each station. For example, model and observations both show that westerly and south-westerly directions are the prevailing wind directions for the stations of CNO, FUL, HHR and ONT. The wind direction is mostly from the southeast at the BUR station, as presented in both observations and simulations. For the wind speed, among the five

stations, the FUL and BUR stations have calm winds, mostly under 6 m/s, while other stations showed stronger wind between 6 - 8 m/s. In general, the WRF simulation underestimates the observed wind speed at HHR and ONT stations. Overall, WRF simulates surface wind speed and direction reasonably well as shown in the wind roses.

Model Performance Evaluation: Planetary Boundary Layer Height

Time series of hourly PBLH from ceilometer measurements and WRF simulations at ONT and IRV during July 2018 are shown in Figure II-3-24. Simulated PBLHs generally showed good agreement with ceilometer derived PBLHs except for very high reported PBLH values (> 2 km). These very high PBLH measurements may have been measurements artifacts caused by cloud interference in ceilometer profiles. Time series of average PBLH diurnal variation from measurements and WRF simulations for the summer season (June-August 2018) at ONT and IRV are shown in Figure II-3-25. The diurnal cycle in PBL height was well captured by the simulations. For example, at ONT, both measured and simulated PBLHs were lowest during early morning, increased to maximum values of ~ 800 m at midday due to stronger convection and vertical mixing, and then slowly decayed to lower heights during the late afternoon and early night. Usually, the days with lower PBL height will lead to lower ventilation of air pollutions, and higher PBL height will help with dispersion of surface pollutions.

Sensitivity Test of Planetary Boundary Layer Scheme

A set of WRF sensitivity simulations regarding the planetary boundary layer scheme was conducted. The planetary boundary layer scheme of Asymmetric Convective Model version 2 (ACM2)⁶ (Pleim, J. E., 2007) was tested in the WRF model. Comparing this set of sensitivity simulations with the simulation with YSU planetary boundary layer scheme, statistical results for temperature, water vapor and wind predictions are similar for both winter and summer seasons. The ACM2 PBL scheme showed slightly better performance for temperature and water vapor mixing ratio comparing with the YSU PBL scheme. The

YSU PBL scheme had marginally better performance for wind speed and the ACM2 PBL scheme has small lower bias for wind speed.

	WS RMSE (kg/kg)	1.8	1.6	1.5	1.9

The performance of the WRF simulations with ACM2 PBL scheme is summarized in Table II-3-3 for 4 quarters of 2018. All the results shown in Table II-3-3 are averaged values for the 15 airport weather stations. Overall, the results from YSU PBL scheme and YSU PBL scheme are consistent with each other with small discrepancies. Both WRF simulations proved representative meteorological fields that well characterized the observed values in summer and winter of 2018.

FIGURE II-3-29

TIME SERIES OF HOURLY WATER VAPOR MIXING RATIO FROM MEASUREMENTS AND WRF SIMULATIONS AT HAWTHORNE (HHR) STATION FOR JANUARY 2018 AND JULY 2018

The surface level model performance comparison between the YSU PBL scheme and ACM2 PBL scheme were evaluated for each month at airport stations in the model domain for January through December 2018. For simplicity, only one summer month (July) and one winter month (January) are shown in Figure II-3-26 through Figure II-3-29. Two stations were selected as examples for surface level model performance evaluation: CNO and HHR. The station of CNO represents inland area and the station of HHR represents coastal climate. In general, the two sets of WRF simulations generated similar hourly temperature and water vapor mixing ratio at each station. The WRF simulations with ACM2 PBL scheme have slightly higher daily maximum temperatures during winter, while it shows warm bias during summertime in the coastal station of HHR. For water vapor mixing ratio, the WRF simulations with ACM2 PBL scheme showed lower values comparing with the WRF simulations with YSU PBL scheme. In all, the performance of WRF with ACM2 PBL scheme is very close to WRF with YSU PBL scheme and the

WRF with YSU PBL scheme was used as the primary model platform to generate meteorological fields for the ~~Draft-PM_{2.5} plan~~ Plan.

FIGURE II-3-30

WIND ROSE FROM MEASUREMENT AND WRF SIMULATION AT FULLERTON (FUL) STATION FOR THE ENTIRE YEAR OF 2018

The measured and WRF simulated wind rose at the station of FUL for 1-year period of January – December 2018 are shown in Figure II-3-30. In general, the WRF simulations with ACM2 reproduces the dominant wind direction as the measurement. For example, model and observations both show that westerly and south-westerly directions are the prevailing wind directions for the stations of FUL. In general, the WRF with ACM2 PBL scheme simulates surface wind speed and direction reasonably well as shown in the wind roses, although the simulation show slightly more underestimates of the observed wind speed comparing with the WRF simulations with YSU PBL scheme.

FIGURE II-3-31

TIME SERIES OF HOURLY PBLH FROM CEILOMETER MEASUREMENTS AND WRF SIMULATIONS FOR JULY 2018 AT ONTARIO (ONT) STATION AND AT IRVINE (IRV) STATION

FIGURE II-3-32

TIME SERIES OF HOURLY PBLH FROM CEILOMETER MEASUREMENTS AND WRF SIMULATIONS FOR DECEMBER 2018 AT ONTARIO (ONT) STATION AND AT IRVINE (IRV) STATION

Time series of hourly PBLH from ceilometer measurements and WRF simulations at ONT and IRV during December 2018 are shown in Figure II-3-32. The simulation with ACM2 PBL scheme showed higher daily maximum PBL and this pattern is consistent with the simulated higher daily maximum temperature comparing with the simulations with YSU PBL scheme.

Summary

The performance of the WRF simulations for the year of 2018 is evaluated with observations from airport weather stations and PBL height measurement from ceilometers. Overall, WRF simulations for each season provided representative meteorological fields that well characterized observed conditions in 2018. Regarding different option of planetary boundary layer scheme, set of WRF sensitivity simulations of Asymmetric Convective Model version 2 (ACM2) was conducted. Comparing this set of sensitivity simulations with the simulation with YSU planetary boundary layer scheme, statistical results for temperature, water vapor and wind predictions are similar for both winter and summer seasons. The ACM2 PBL scheme showed slightly better performance for temperature and water vapor mixing ratio comparing with the YSU PBL scheme. The YSU PBL scheme had marginally better performance for wind speed and the ACM2 PBL scheme has small lower bias for wind speed. Since the modeling discrepancies between different PBL height scheme are very small, the meteorological fields obtained with WRF simulations with YSU PBL scheme are used as meteorological inputs for CMAQ modeling of PM_{2.5} in this plan.

MODELING EMISSIONS, BOUNDARY CONDITIONS, AND INITIAL CONDITIONS

Modeling Emissions Inventory

Inventory Profile

Temporal and Spatial Allocations of Emissions

Boundary and Initial Conditions

Modeling Emissions Inventory

Table II-4-1 provides the baseline and controlled modeling emissions inventories that are consistent with the emissions used in the attainment demonstration and alternative analyses. The CMAQ simulations were based on the annual emissions inventory, with adjustments made for source-specific temporal profiles and daily temperature variations. An extensive discussion of the overall emissions inventory is provided in Appendix I. Approaches used in generating gridded hourly emissions for each modeling day are presented in this Chapter.

Inventory Profile

This section discusses the baseline modeling inventories for the base year 2018 and the future years 2025 and 2030, as outlined in the Draft PM_{2.5} Plan. The primary focus of this plan is to demonstrate attainment of the 2012 annual PM_{2.5} National Ambient Air Quality Standard (NAAQS) set at 12 µg/m³.

The baseline emissions projection assumes no additional emission controls beyond the measures and programs already in place. These projections consider emissions resulting from population growth, increased vehicle miles traveled (VMT), and the implementation of all previously adopted rules and regulations. The cut-off date for South Coast AQMD regulations is October 2020 (except for Rule 1109.1, adopted in November 2021), and for CARB's regulations, the cut-off date is December 2021. Controlled emission projections reflect the anticipated benefits of implementing control measures in relation to future baseline emissions. Comprehensive descriptions of these control measures can be found in Chapter 4 and Appendix IV of the Draft PM_{2.5} Plan report. For further details on emission sources, readers can refer to Appendix I which contains emission summary reports categorized by source for both the base year and future baseline scenarios used in this modeling analysis. Detailed summaries of emissions

reductions by source category for future (2025 and 2030) controlled scenarios are available in Attachment 3 of Appendix II.

Temporal and Spatial Allocations of Emissions

Point, mobile, and area emissions inventories specific to each day were generated for the base year 2018. On-road mobile source emissions were calculated using data from SCAG transportation modeling, CARB's EMFAC2021 emissions rates, observed daily traffic fluctuations, and modeled daily temperature variations. To create day-specific hourly emissions, annual emissions were distributed using temporal profiles. Each source type was assigned profiles for monthly throughputs, day-of-week variations, and diurnal changes.

Point source emissions were allocated spatially based on the precise locations of emitting facilities. Conversely, countywide emissions stemming from area and off-road sources were distributed using spatial surrogates. For this purpose, a comprehensive set of over 110 spatial surrogates was employed, a compilation refined by CARB during each AQMP development cycle. Each emissions source, identified by its Emission Inventory Code, was associated with an appropriate surrogate profile. These surrogates represented a diverse range of sources, encompassing gas stations, landfills, military bases, single-family homes, and railyards. In alignment with our established AQMP practices, socioeconomic data for both the base and future years, incorporating population, employment, and housing statistics, as provided by SCAG during its RTP/SCS process, were incorporated into these surrogates. Further elaboration on the temporal and spatial allocation of on-road and total emissions are provided in following sections.

On-road Mobile Emissions

On-road mobile sources are responsible for a large fraction of the total VOC, NO_x, CO, NH₃ and PM_{2.5} emissions in our modeling domain. These emission sources are highly dependent on both time and location, with variations up to a factor of 8 between overnight and peak traffic hours at specific locations. On-road mobile emission patterns also exhibit substantial variation throughout the week and year, influenced by factors such as special events, holidays, and weather conditions. Location-specific variations may also arise due to proximity to high-employment areas, sporting events, or/and seasonal activities.

Real-time traffic flow measurements from 2018 were used to apportion traffic volumes on an hourly basis throughout the five counties (Ventura, Los Angeles, Orange, Riverside and San Bernardino). These measurements include data from thousands of sensors scattered throughout the Basin, covering both light- and heavy-duty vehicle flow. Given the limited availability of monitoring data in the five outlying counties (San Luis Obispo, Santa Barbara, Kern, Imperial, and San Diego), grid-based on-road emissions

were generated for those regions using generic traffic profiles that account for variations by day of the week (Kwon et al., 2003)¹.

In Figures II-4-1 to II-4-4, we compare daily on-road emissions of NO_x, Primary Elemental Carbon (PEC), Primary Organic Carbon (POC), and CO between the 2022 AQMP estimated with EMFAC2017 (blue) and the ~~Draft~~ PM_{2.5} ~~plan~~ Plan estimated with EMFAC2021 (orange) over the south coast air basin (SCAB) in 2018. On-road emissions estimated with EMFAC2021 exhibit very similar daily/weekly patterns and seasonal variation as those estimated with EMFAC2017. Despite of the similar temporal variation in emissions in the two models, EMFAC2021 estimates higher NO_x (higher by 10% on average) and CO (higher by 24% on average) emissions compared to EMFAC2017 whereas it estimates noticeably lower POC emissions than EMFAC2017 (lower by 38% on average). PEC estimated with the two emission models (EMFAC2017 and EMFAC2021) are comparable (differs by 5% on average). The higher estimates of NO_x and CO in EMFAC2021 compared to EMFAC2017 are mostly because new vehicle emissions test data show that light-duty vehicles have higher exhaust emissions and updated DMV data for 2018 indicate that medium heavy-duty trucks are older than what was assumed in EMFAC2017. The lower primary particulate emissions (PEC and POC) in EMFAC2021 compared to EMFAC2017 can be attributed to the model updates on emissions and speed correction factors for brake wear that are obtained from new emission tests.

Emissions Profiles

Day specific emissions were generated for 2018. Figure II-4-5 illustrates the total daily emissions of NO_x, NH₃, and Primary PM_{2.5} contained in the CMAQ modeling domain during the base year of 2018. Note that the emissions totals are much higher than those presented in Table II-4-1. This is because the values in Table II-4-1 represent basin-wide total emissions while those in Figure II-4-5 comprise totals from the entire modeling domain. The profile clearly depicts a changing emissions pattern with two distinct cycles represented: a weekly cycle, illustrated by Sunday through Saturday peaks and valleys, and day-to-day variations in emissions within the weekly cycle. Daily variations are primarily driven by daily vehicular activities and ambient temperature and humidity changes. Although not included in Figure II-4-5, spatially and temporally resolved emissions from prescribed fires were also included in the emissions in the modeling domain. The attainment demonstration does not include emissions from wildfires.

FIGURE II-4-5

2018 DAILY EMISSIONS OF NO_x, NH₃, AND PRIMARY PM_{2.5} IN THE MODELING DOMAIN.

Spatial Distribution

Figures II-4-6 through V-4-8 illustrate the spatial distribution of on-road emissions for primary PM_{2.5}, NO_x, and NH₃ in the modeling domain. Figures II-4-9 through II-4-11 show the spatial distribution of total emissions from all sources for these key primary pollutants across the entire modeling domain. The maps reveal that on-road emissions tend to cluster in urban areas, such as the downtown areas of Los Angeles, San Diego, and Long Beach, as well as along major arterial highways like I-5 and I-15. This concentration results from the high density of vehicles and substantial traffic volumes in these regions. When examining the total emissions of these key pollutants, urban centers emerge as major sources, characterized by their high population density and significant anthropogenic activities, including heavy transportation and various industrial and commercial operations. Notably, the spatial distribution of primary emissions also highlights elevated emissions in Mexican cities near the US-Mexico border. These emissions from across the border can influence background pollutant levels and directly impact Southern California's air quality, particularly under specific meteorological conditions, such as southerly winds during the summer, which facilitate the transport of air pollution across borders.

Biogenic Emissions

Biogenic VOC emissions were calculated at an hourly frequency using the Model of Emissions of Gases and Aerosols from Nature version 3.0 (MEGAN3.0) with 2018 meteorological data as input (simulated with WRFv4.4.2). MEGAN was employed in its default configuration, with the exception of the normalized Leaf Area Index (LAIv) input. The LAIv input we used here was developed by the California Air Resources Board and was derived from 2018 data obtained from the Moderate Resolution Imaging Spectroradiometer (MODIS) on NASA's Terra and Aqua satellites. In urban areas where MODIS data were unavailable, LAIv was based on tree survey data from the US Forest Service. Figure II-4-12 illustrates the daily total emissions of biogenic VOC, in tons per day, within the Basin. The trend shows higher emissions during spring and summer months, with multiple peaks occurring from June to August, coinciding with periods of high temperatures. Table II-4-1 shows the total emissions from biogenic sources within the Basin.

Basin-wide Emissions (tons/day)	135.1	132.1	5.3

Boundary and Initial Conditions

We utilized the Community Atmosphere Model with Chemistry (CAM-chem; Emmons et al., 2020)², a component of the National Center for Atmospheric Research (NCAR) Community Earth System Model (CESM), to generate boundary conditions (BCONs) for our modeling domains. Specifically, CAM-chem provided BCONs for the 12 km statewide Community Multi-scale Air Quality (CMAQ) domain, while the boundary conditions for the 4 km inner South Coast domain were derived from the 12 km CMAQ output.

CAM-chem is a well-established global atmospheric model known for simulating tropospheric and stratospheric compositions. We extracted boundary conditions encompassing inorganic gases, volatile organic compounds (VOCs), and aerosol species such as elemental carbon, organic matter, sulfate, and nitrate from CAM-chem simulations conducted in 2018³. These CAM-chem simulation results are publicly accessible at <https://www.acom.ucar.edu/cam-chem/cam-chem.shtml>. To prepare this data for integration into the CMAQ model, we used the 'mozart2camx' computer program, originally designed for processing outputs from the MOZART global model. Some modifications were made to adapt it for CAM-chem output processing.

Vertical layering in the BCON data adheres to the meteorological files, utilizing pressure levels at each layer interface for vertical interpolation. For horizontal alignment, bilinear interpolation was applied to interpolate data from the global model grids to the regional CMAQ grids. Speciation profiles were employed to map CAM-chem species into CMAQ species for trace gases (SAPRC07TC) and aerosols. The final CAM-chem derived BCONs for the CMAQ domain represent day-specific mixing ratios, varying in spatial (horizontal and vertical) and temporal (every 6 hours) dimensions.

Total PM_{2.5} Mass in Boundary Conditions

Figures II-4-13 and II-4-14 illustrate daily averages of surface total PM_{2.5} along the four boundaries of our modeling domain. The mean surface PM_{2.5} levels along the southern and northern boundaries exhibit similarities, typically ranging from 1 to 6 µg/m³. Notably, there are periodic peaks in PM_{2.5} concentrations (ranging from 6 to 10 µg/m³) along the southern boundary during the summer season, possibly attributed

² Emmons, L. K., Schwantes, R. H., Orlando, J. J., Tyndall, G., Kinnison, D., Lamarque, J.-F., et al., (2020). The Chemistry Mechanism in the Community Earth System Model version 2 (CESM2). Journal of Advances in Modeling Earth Systems, 12, e2019MS001882, <https://doi.org/10.1029/2019MS001882>

³ Buchholz, R. R., Emmons, L. K., Tilmes, S., & The CESM2 Development Team, (2019). CESM2.1/CAM-chem Instantaneous Output for Boundary Conditions. UCAR/NCAR - Atmospheric Chemistry Observations and Modeling Laboratory. <https://doi.org/10.5065/NMP7-EP60>.

to regional transport from Mexico when southerly winds prevail. In contrast, the northern boundary is influenced by emissions from central California, resulting in a seasonal average surface PM_{2.5} concentration of approximately 3-4 $\mu\text{g}/\text{m}^3$. The western boundary, situated over the Pacific Ocean west of the Basin, consistently shows the lowest concentrations, with an average PM_{2.5} concentration peaking in summer and fall seasons ($\sim 3 \mu\text{g}/\text{m}^3$) and dropping in spring ($\sim 2 \mu\text{g}/\text{m}^3$).

The eastern boundary, on the other hand, exhibits a broader range, with average PM_{2.5} concentrations ranging from 2 to 12 $\mu\text{g}/\text{m}^3$. These concentrations tend to be higher than those observed along other boundaries, particularly during the summer months. This difference may be attributed to elevated background particulate levels resulting from wildfires and biogenic sources originating from the eastern region. Additionally, the prevailing general circulation in Southern California moves from west to east, causing the eastern boundary to experience a higher background level of PM_{2.5} due to the influence of upwind emissions compared to other boundaries. The peak of PM_{2.5} ($>12 \mu\text{g}/\text{m}^3$) occurred in June at the eastern boundary is likely attributed to a wildfire event.

FIGURE II-4-13

DAILY AVERAGES OF SURFACE PM_{2.5} CONCENTRATION ALONG THE SOUTH AND NORTH BOUNDARIES

FIGURE II-4-14

DAILY AVERAGES OF SURFACE PM_{2.5} CONCENTRATION ALONG THE WEST AND EAST BOUNDARIES

Figures II-4-15 through II-4-18 depict vertical profiles of seasonal PM_{2.5} concentrations, extending from the ground surface to the mid-troposphere, along the four boundaries of our modeling domain. In all seasons, PM_{2.5} is predominantly concentrated within the atmospheric boundary layer, with background PM_{2.5} levels above the boundary layer typically below 2 µg/m³. Both near-surface PM_{2.5} and background PM_{2.5} in the free troposphere peaks in the summer months along all four boundaries. This phenomenon is likely attributable to increased secondary production under warm and humid summer conditions. The most notable disparity between near-surface (or boundary layer) and free-tropospheric PM_{2.5} concentrations occurs during winter due to reduced vertical mixing and ventilation compared to warmer seasons.

Both near-surface and free-tropospheric PM_{2.5} concentrations are higher along the eastern boundary compared to the other boundaries. This disparity arises from downwind transport and greater influences from wildfires and biogenic matter compared to the other boundaries. Conversely, the western boundary consistently has the lowest PM_{2.5} levels within both the boundary layer and free troposphere due to the relatively cleaner airflow originating from the ocean.

FIGURE II-4-16

PM_{2.5} VERTICAL PROFILE ALONG THE NORTHERN BOUNDARY IN FOUR SEASONS

FIGURE II-4-18

PM_{2.5} VERTICAL PROFILE ALONG THE EASTERN BOUNDARY IN FOUR SEASONS

The boundary values used in future year simulations were retrieved using the same approach as in the base year (2018), except for anthropogenic emissions, which were adjusted based on the projected future

emission levels in the State. In this approach, out of state emissions were not adjusted due to the lack of accurate information, but the impact of statewide emission reductions was considered.

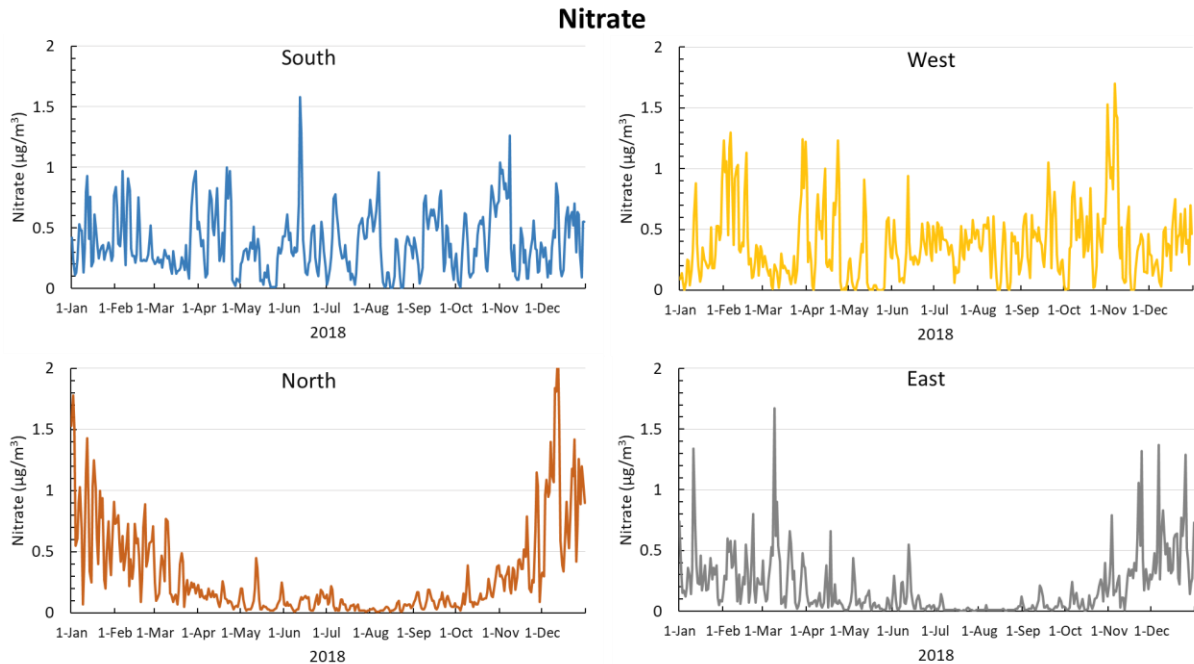

PM_{2.5} Species in Boundary Conditions

We further examine the boundary and initial conditions of several major PM_{2.5} species, including nitrate, sulfate, elemental carbon (EC), and organic carbon (OC). Figures II-4-19 and II-4-22 illustrate daily averages of these PM_{2.5} species along the four boundaries of our modeling domain. The boundary conditions exhibit significant variations across four different directions and among various PM_{2.5} species. OC emerges as the predominant PM_{2.5} species along all four boundaries, with annual average concentrations ranging from 0.72 to 1.88 $\mu\text{g}/\text{m}^3$. This is followed by sulfate (0.43-0.73 $\mu\text{g}/\text{m}^3$), nitrate (0.30-0.38 $\mu\text{g}/\text{m}^3$), and EC (0.05-0.19 $\mu\text{g}/\text{m}^3$). Table II-4-2 provides an overview of the annual averages of PM_{2.5} species along these four boundaries.

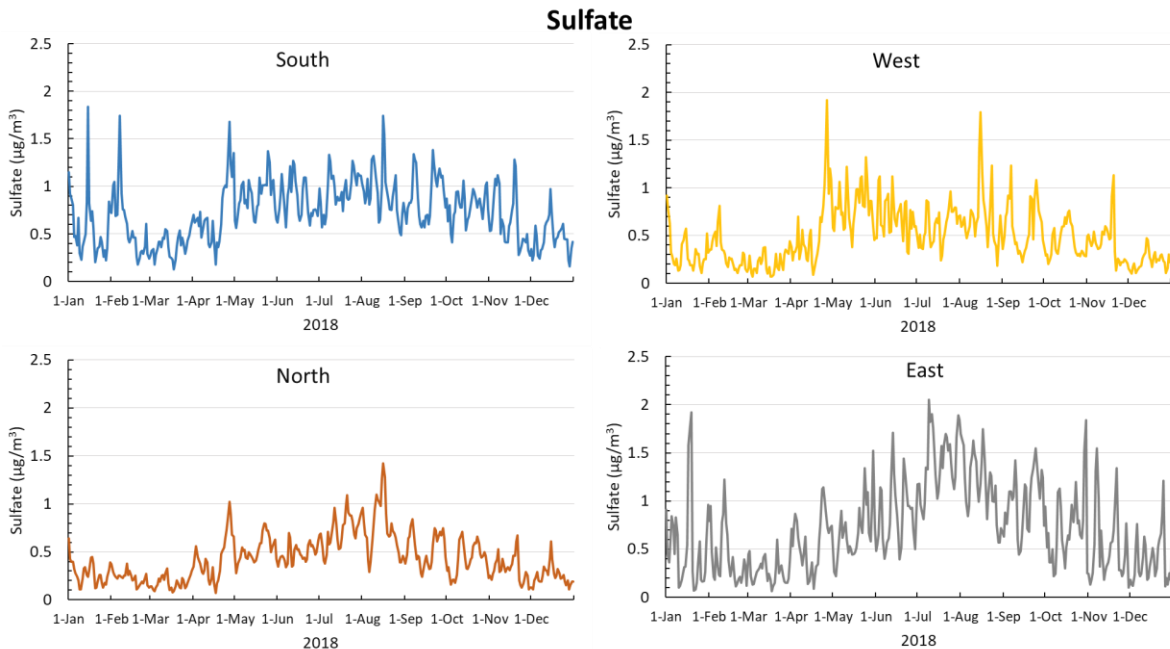

Nitrate and sulfate levels are at their highest along the southern boundary due to anthropogenic emissions originating from cities in Southern California and Mexico (Figures II-4-19 and II-4-20). However, at the western boundary, nitrate and sulfate concentrations are comparable to the levels in other boundary directions. This is possibly attributed to various factors, including transport by land-sea oscillations, long-range transport from Asia, and marine/ship emissions. EC concentrations peak at the southern and eastern boundaries due to anthropogenic emissions from Mexico and wildfires occurring in the western U.S. states (Figure II-4-21). OC exhibits higher levels at the northern and eastern boundaries, possibly due to the influence of wildfires and biogenic sources. Compared to nitrate, sulfate, and EC, OC generally has a shorter atmospheric lifetime and thus is closer to its sources than other species (e.g., Cheung et al., 2011)⁴. Therefore, unlike other species, OC concentrations are at their lowest along the western boundaries (Figure II-4-22), owing to the relatively clean airflow originating from the ocean.

When comparing PM_{2.5} species to gaseous pollutants such as NO_x, it's worth noting that particulate matter has a longer atmospheric lifetime. This extended lifetime allows PM_{2.5} species to disperse more evenly across different boundaries than most gaseous pollutants. In contrast, gaseous pollutants like NO_x show substantial concentration variations across boundaries, with notably low levels at the western boundary (close to zero) and comparatively higher levels at other boundaries (Figure not shown).

ANNUAL PM2.5 ATTAINMENT DEMONSTRATION

Introduction

Annual PM2.5 Modeling Approach

Performance Evaluation

Base Year Annual PM2.5

Future Year Annual PM2.5 Air Quality

Unmonitored Area Analysis

Summary and Conclusions

Introduction

On April 15, 2015, the South Coast Air Basin was designated a ‘moderate’ non-attainment area for the 2012 annual PM_{2.5} standard of 12 µg/m³. This designation set an attainment deadline of December 31, 2021, based on CAA subpart 4, which establishes that attainment must be reached by the end of the 6th calendar year after the effective date of “moderate” designation. Acknowledging the challenges in meeting the standard, including the feasibility of proposed measures, uncertainties in drought conditions, and the potential inability to credit all ozone strategy reductions towards PM_{2.5} attainment if approved under CAA Section 182(e)(5), South Coast AQMD requested a voluntary bump-up to the “serious” classification, with a new attainment date of 2025. On December 9, 2020, U.S. EPA reclassified the Basin from “moderate” to “serious” nonattainment for the 2012 annual PM_{2.5} NAAQS with an attainment deadline by December 31, 2025.¹ “Serious” nonattainment areas are required to attain the standard as expeditiously as practicable, but no later than the end of the tenth calendar year after the designation, i.e., December 31, 2025. Under CAA Section 188(e), “serious” nonattainment areas may request an attainment date extension to no later than the end of the fifteenth calendar year after the designation, i.e., December 31, 2030. This plan requests an extension of attainment in 2030 due to unforeseen challenges associated with near-road monitored PM_{2.5} levels, lack of progress from the sources subject to federal and international sources and adverse meteorology.

PM_{2.5} FRM Sampling

The South Coast AQMD maintains a sampling network of Federal Reference Method (FRM) PM_{2.5} monitors at 20 sites throughout the Basin and Coachella Valley. This network is supplemented by Federal Equivalent Method (FEM) continuous PM_{2.5} monitors at a subset of these locations to report real-time data to the public and to feed for forecasting algorithms. FRM samplers pull ambient air through a filter over a 24-hour period. The filter is then removed and weighed to determine ambient PM_{2.5} concentrations during the sampling period. The FEM samplers used by South Coast AQMD are Beta Attenuation monitors that report hourly PM_{2.5} concentrations continuously, which are averaged over a 24-hour period to determine daily averages. While measurements from FRM and FEM produce similar concentrations, there still is some variation, with FEM samplers typically reading higher than collocated FRM samplers. FRM measurements are used in the determination of attainment status, whereas FEM measurements are used to supplement FRM measurements for days with missing data, if the FEM monitor is determined to be eligible for NAAQS comparison by U.S. EPA. The calculation of 5-year-weighted base year design values used FRM samples with missing FRM samples replaced by NAAQS-comparable FEM samples.

Speciated PM_{2.5} Sampling

South Coast AQMD adopted a Multi-Channel Fine Particulate (MCFP) sampling system for the PM₁₀ Technical Enhancement Program (PTEP) monitoring program in 1995.¹ New PM samplers, speciated air sampling system (SASS) samplers, were deployed at the four Chemical Speciation Network (CSN) sites in the Basin. The SASS sampler collects PM_{2.5} particles on 47mm quartz and Teflon filters simultaneously within the same sampler continuously for 24-hours for subsequent laboratory chemical analysis. Samples were originally collected one out of every six days.

PM_{2.5} speciation data, measured as individual species at the four CSN sites in the Basin during the period 2017-2019, provided the PM_{2.5} chemical characterization for evaluation and validation of the CMAQ annual modeling. The four CSN sites include Riverside-Rubidoux, Fontana, Anaheim and Central Los Angeles (Figure II-5-1). These four sites represent each county that the monitor is located in. PM_{2.5} mass, ions, organic and elemental carbon, and metals, for a total of 43 chemical species, were analyzed from a one-in-six-day sampling schedule at the 4 sites. The speciation profiles in these four sites are used to estimate the speciation profiles at the other monitoring stations using interpolation with inverse distance weighting per U.S. EPA's guidance.

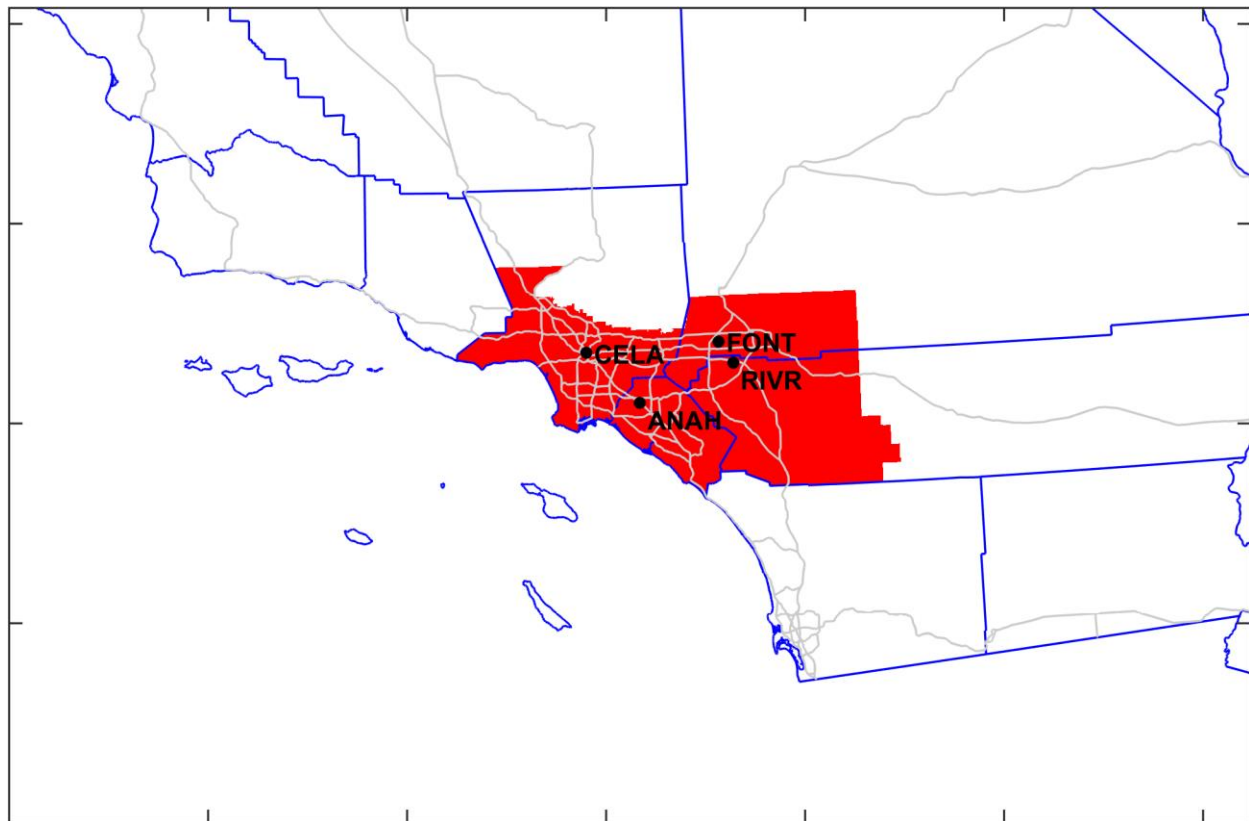

FIGURE II-5-1

SAMPLING SITES IN THE BASIN

PM_{2.5} speciation data measured by the SASS samplers are used to derive the species fractions required for the PM_{2.5} attainment demonstration methodology. U.S. EPA's PM_{2.5} modeling guidance recommends calculating future year PM_{2.5} design values by multiplying quarterly, species-specific Relative Response Factors (RRFs) with the base year speciated design values for each quarter for each monitoring site. Base year design values are determined from the FRM mass data, however the FRM filters are not chemically speciated. Therefore, the guidance document recommends multiplying the species fractions that are measured in a speciation sampler such as the SASS to the FRM mass data to derive chemically speciated design values for the FRM data. Discussion in the measured design values and the calculation of speciation profiles is presented later in this chapter.

Annual PM2.5 Modeling Approach

This PM2.5 Plan’s annual PM2.5 modeling follows the U.S. EPA modeling guidance² to estimate the future year annual PM2.5 levels, which is based on the site and species-specific RRF approach. A five-year weighted quarterly average from the 2016 to 2020 period was established as the base year 2018 design value. The year 2020, however, was excluded in calculation of 2018 base year design values due to exceptionality of 2020. Refer to Chapter 5 for more details.—on the formulation of the modified 5-year weighted design value.

The year 2020 was characterized by a large disruption in air pollutant emissions due to the response to the COVID-19 pandemic and by the exceptionally widespread wildfire activity in the state. The COVID-19 Pandemic started to influence economic activity in March of 2020 in the South Coast AQMD region. During the initial months of “safer at home” orders in late March to June 2020, light-duty and heavy-duty vehicle traffic decreased by 43 percent and 26 percent, respectively, with respect to the month before the COVID stay-at-home measures began. In addition, cargo movement at the ports of Los Angeles and Long Beach decreased by 12 percent, and flights in major airports in the Basin decreased by over 50% during April to June, compared to the same period in 2019. Activity at the ports and airports remained significantly below the business-as-usual level in 2020. Wildfires are a significant source of both fine particulate matter and VOCs. Additional VOC emissions from wildfire activity may lead to increases in secondary PM2.5 throughout the Basin. The 2020 fire season was extremely active, with a record amount of acreage burned. Over 4 million acres burned in California in 2020, more than double the previous modern record set in 2018. Both fires within the South Coast Air Basin such as the Bobcat, El Dorado, Silverado, Blue Ridge, Ranch2, Apple and Snow fires and fires in Northern and Central California affected air quality in 2020. In total, we identified 13 events that potentially affected PM2.5 concentrations in the Basin and that triggered smoke advisories for the Basin.³ These 13 events, listed in Attachment 4 of this appendix, spanned for long periods from mid-June through mid-December. Accordingly, it is unreasonable to use such extraordinary circumstances impacting human activities and associated emissions in a SIP planning which is based on business-as-usual normal situation. More discussions on the COVID-19 impacts, meteorology and wildfire impacts in relation with ozone can be found in Chapter 2 of the 2022 AQMP.

The modeling platform is developed to model an entire year to calculate quarterly PM2.5 averages. A day-specific emissions inventory was developed to reflect the temperature and relative humidity dependency of mobile sources and biogenic emissions. Also, seasonal fuel switching, and the resulting emission rates were incorporated in the modeling inventory.

In addition to the base year (2018), future milestone years simulated under this plan were 2025 and 2030, with the former being the target attainment year for a ‘serious’ non-attainment area and the latter for an extended attainment deadline for a ‘serious’ non-attainment area. Both baseline and control scenarios were simulated for each of the future years. CMAQ output was averaged over the 3X3 grid around each monitoring station following U.S. EPA’s modeling guidance.

² Modeling Guidance for Demonstrating Attainment of Air Quality Goals for Ozone, PM2.5, and Regional Haze, U.S. EPA, November 2018. Available at: https://www.epa.gov/sites/default/files/2020-10/documents/o3-pm-rh-modeling_guidance-2018.pdf

³ Smoke advisories released in 2020 available here: <https://www.aqmd.gov/home/news-events/news-and-media/2020-news-archives#>

The base year design values are listed in Table II-5-1. The future year design values are calculated using the base year quarterly averages and the RRF calculated using modeled concentrations for the base year and future scenario. Site- and species-specific RRFs are calculated from CMAQ simulations and then, they are applied to the quarterly average design values which are averaged for the period of 2016 to 2019 using the 5-year weighted average approach. The average of the quarterly species-specific projections is the future design value.

Performance Evaluation

The EPA guidance assesses model performance on the ability to predict both PM_{2.5} component species concentrations and the total mass. No specific performance criteria thresholds are recommended in EPA's modeling guidance document. This is because the model uses relative response factors rather than direct predictions to forecast future concentrations. Performance is evaluated by examining key statistics and graphical representations of differences between model-predicted concentrations and observations. The statistics examine model bias and error, while graphical representations of model prediction as a function of time and concentration scatter plots supplement the model performance evaluation. The CMAQ modeling results presented for each station are based on the same "1-cell" basis, as recommended by the guidance.

For the CMAQ performance evaluation, the modeling domain is separated into several sub-regions or zones. Figure II-5-2 depicts the sub-regional zones used for base-year simulation performance. The different zones present unique air quality profiles. The Basin is represented by five zones: "Coastal", "San Fernando", "Foothills", "Urban Source", and "Urban Receptor". The "Urban Receptor" region typically has the highest PM_{2.5} concentrations in the Basin. Table II-5-2 lists the stations, their abbreviations, and their assigned performance evaluation zone.

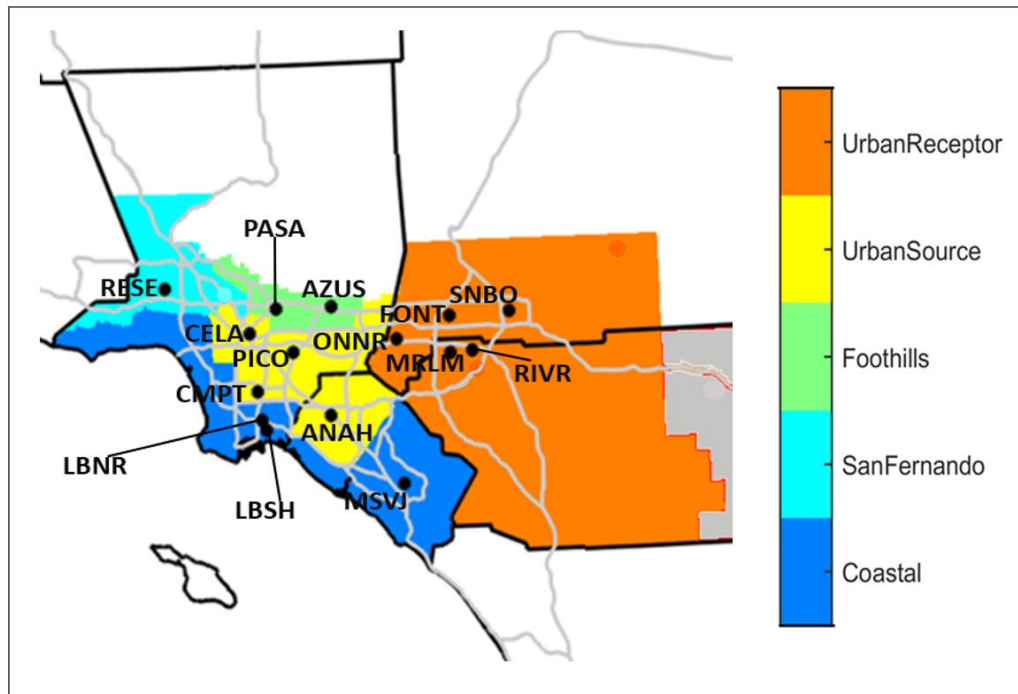

FIGURE II-5-2

PERFORMANCE EVALUATION ZONES. BLACK DOTS INDICATE THE LOCATION OF FRM STATIONS.

TABLE II-5-2
FRM STATIONS IN THE SOUTH COAST AIR BASIN

	Station Location	Station Abbreviation	Performance Evaluation Zone
	Long Beach	LGBH	Coastal
	Mission Viejo	MSVJ	Coastal
	South Long Beach	SLBH	Coastal
	Azusa	AZUS	Foothills
	Pasadena	PASA	Foothills
	Reseda	RESE	San Fernando
	Fontana	FONT	Urban Receptor
	Mira Loma	MRLM	Urban Receptor
	Ontario	ONFS	Urban Receptor
	Riverside	RIVR	Urban Receptor
	San Bernardino	SNBO	Urban Receptor
	Anaheim	ANAH	Urban Source
	Compton	CMPT	Urban Source
	Los Angeles	CELA	Urban Source
	Pico Rivera	PICO	Urban Source

Daily predicted and observed PM_{2.5} concentrations at CELA, ANAH, FONT, MRLM, and RIVR are presented in Figures II-5-3 through II-5-7. While absolute concentrations may differ, the model simulates trends in PM_{2.5} reasonably well. Both modelled and observed PM_{2.5} concentrations have high variability and display the highest peaks in the 1st and 4th quarter. Concentrations have less day-to-day variation in the 2nd and 3rd quarters at all the 5 sites. This behavior is likely due to differences in meteorology throughout the year. Weather patterns during the first quarter and the second half of the 4th quarter are typically highly variable; precipitation days, cold, high-winds and unstable conditions associated with synoptic scale storms are all commonly experienced during the winter months. On the contrary, spring and summer weather patterns are dominated by high pressure systems, leading to less day-to-day variation in boundary layer heights and wind speeds.

Statistical Evaluation of Total PM2.5 mass

CMAQ over-predicts total PM2.5 mass in the “Coastal”, “Foothills” and “Urban Source” regions. The “San Fernando”, “Urban Receptor” regions, are well represented by CMAQ in the base year. The “Urban Receptor” region typically contains the highest PM2.5 concentrations in the South Coast Basin. Statistical measures to evaluate the modeling performance in each geographical zone are provided in Table II-5-3.

The statistics used to evaluate the daily CMAQ PM2.5 performance include the following:

<u>Statistic</u>	<u>Equation</u>	<u>Definition</u>
Bias Error	$BiasError = \frac{1}{N} \sum (Obs - Pred)$ <p>where “N” is the number of values.</p>	Average of the differences in observed and predicted daily values. Negative values indicate under-prediction.
Normalized Bias Error	$NormBiasError = \frac{1}{N} \sum \left(\frac{Obs - Pred}{Obs} \right) \cdot 100$	Average of the quantity: absolute difference in observed and predicted daily values normalized by the observed daily concentration
Gross Error	$GrossError = \frac{1}{N} \sum Obs - Pred $	Average of the absolute differences in observed and predicted daily values
Normalized Gross Error	$NormGrossError = \frac{1}{N} \sum \left \frac{Obs - Pred}{Obs} \right \cdot 100$	Average of the quantity: absolute difference in observed and predicted daily values normalized by the observed daily concentration

TABLE II-5-3

QUARTERLY STATISTICAL ANALYSIS OF TOTAL PM_{2.5} MASS FOR EACH OF THE SIX ANALYSIS ZONES

Region	Quarter	Mean Sim. ($\mu\text{g}/\text{m}^3$)	Mean Obs. ($\mu\text{g}/\text{m}^3$)	Bias Error ($\mu\text{g}/\text{m}^3$)	Norm Bias (%)	Gross Error ($\mu\text{g}/\text{m}^3$)	Norm Gross (%)
Coastal	Q1	15.4	11.1	-4.3	-60.9	5.9	67.5

San Fernando	Q1	9.4	8.5	-1.0	-12.2	2.5	34.0
San Fernando	Q2	9.2	10.4	1.2	-1.0	2.4	31.3
San Fernando	Q3	9.4	12.1	2.7	11.3	4.1	31.0
San Fernando	Q4	12.2	11.2	-1.0	-22.7	4.8	42.2
San Fernando	Annual	10.1	10.5	0.4	-7.5	3.5	35.1
Urban Receptor	Q1	14.0	12.1	-1.9	-17.6	4.3	39.0
Urban Receptor	Q2	10.1	12.2	2.1	13.0	3.1	25.6
Urban Receptor	Q3	10.9	14.5	3.7	20.9	4.2	26.4
Urban Receptor	Q4	16.7	14.3	-2.4	-25.7	5.5	49.1
Urban Receptor	Annual	13.0	13.3	0.3	-2.4	4.3	35.1
Urban Source	Q1	17.8	12.2	-5.7	-59.3	7.1	65.6
Urban Source	Q2	10.0	10.5	0.5	3.5	2.5	25.0
Urban Source	Q3	9.7	13.1	3.4	20.4	4.1	27.1
Urban Source	Q4	20.4	13.8	-6.6	-56.8	7.9	65.9
Urban Source	Annual	14.5	12.4	-2.1	-23.1	5.4	45.9

Model performance in the “Urban Receptor” region consistently outperforms the four other regions exhibiting the smaller normalized bias and normalized gross error for the annual analysis. Model performance in the “Urban Receptor” region is also strong when evaluating statistics on a quarterly basis. It is important to model this region accurately, as it contains the stations with the highest PM_{2.5} concentrations in the Basin.

Model Performance of Speciated PM_{2.5} Predictions

Figures II-5-9 through II-5-12 compare predicted and observed particulate sulfate, nitrate, elemental carbon, and organic carbon concentrations for the four stations where speciation data are available (ANAH, CELA, FONT, and RIVR). Note that organic carbon concentrations in the figures are based on direct measurements and are not adjusted with the SANDWICH method.

The model predicts ammonium ion, sulfate, nitrate, EC, and OM reasonably well in general. However, the model tends to overpredict concentrations at Central Los Angeles, which is near major sources of emissions. Conversely, the model tends to underestimate PM_{2.5} species concentrations at inland stations in Fontana and Riverside. Overall, the model captures the relative contributions of PM_{2.5} species reasonably well, showing that OM is the largest contributors to total PM_{2.5}; OM fraction of total PM_{2.5} mass is 44% which agrees with measurements showing 41% of total mass being OM. OM predictions have significantly improved compared to 2016 AQMP values possibly due to the addition of a pseudo-SOA precursor thus increasing the estimates of SOA by CMAQ.

CMAQ SOA Mass Simulation

Traditionally, air quality models tend to underpredict secondary organic aerosols (SOA) concentrations. Mounting evidence from field and laboratory observations coupled with atmospheric model analysis shows that primary combustion emissions of organic compounds exhibit a broad spectrum of volatility, leading to dynamic partitioning of these compounds, especially in the early stages of their atmospheric lifetime (Murphy et al., 2017).⁴ Starting from CMAQ version 5.2, the model accounts for the semi-volatile partitioning and gas-phase aging of these primary organic aerosol (POA) compounds consistent with experimentally derived parameterizations. A new surrogate species termed potential secondary organic aerosol from combustion (pcSOA) was added to the model. It provides a cumulative representation of the SOA from combustion sources that could be missing from current chemical transport model predictions. The reasons for this missing mass likely include:⁵

- Missing intermediate volatility organic compound (IVOC) emissions in current inventories.
- Multigenerational aging of organic vapor products from known SOA precursors (e.g., toluene, alkanes).
- Underestimation of SOA yields due to vapor losses at the walls in smog chamber experiments.
- Organic-water interactions and aqueous-phase processing of known organic vapor emissions.

The result of this new parameterization is a good model performance with respect to measured organic aerosol by CMAQ, as shown in Figures II-5-9 through II-5-12. The quarterly averages of primary organic aerosol (POA) and secondary organic aerosol (SOA) mass concentrations are depicted in Figures II-5-13 to II-5-16 for each station. Generally, POA concentrations are elevated in the first and fourth quarters. This trend is attributed to increased residential fuel combustion during colder months, which contribute to higher POA levels. SOA concentrations are also high in fall and winter due to the formation of SOA from the oxidation of combustion related pollutant emissions, as well as due lower temperatures and higher humidity in winter, that contribute to the accumulation of air pollutants. Some inland stations, such as RESE, FONT, MRLM, ONFS, and SNBO exhibit also high SOA concentrations in the third quarter. These high concentrations can be attributed to increased biogenic volatile organic compound (VOC) emissions in the summer, resulting in higher SOA levels due to the elevated temperatures during this season.

Base Year Annual PM2.5

Quarterly average of PM2.5 FRM mass concentrations, using the modified 5-year weighted average of measurements during 2016-2020 is shown in Figure II-5-17. As shown, among the four stations, Anaheim has the lowest level of PM2.5 concentrations in all quarters, and the highest values occur at Rubidoux (13.50 $\mu\text{g}/\text{m}^3$) and CELA (13.49 $\mu\text{g}/\text{m}^3$) in quarter 4. In general, the sites in the western half of the Basin: Los Angeles and Anaheim, tend to have the highest average levels in the fourth quarter. Rubidoux also presents the highest concentration in the fourth quarter, whereas Fontana experiences the highest concentration in the third quarter. All stations tend to have the lowest concentrations in the first or second quarter. Typically, spring storms and favorable atmospheric dispersion drive PM2.5 concentrations down in the second quarter. Fontana, Rubidoux, and Los Angeles presented the lowest concentrations during the first quarter, whereas Anaheim had the lowest value in the second quarter.

FIGURE II-5-17

QUARTERLY AVERAGE OF PM2.5 FRM MASS CONCENTRATIONS, USING THE MODIFIED 5-YEAR WEIGHTED AVERAGE OF MEASUREMENTS DURING 2016-2020 AT CSN MONITORS.

Speciated Quarterly Average Data

The measurements of individual species obtained from the CSN sites may differ from the retained mass of a specific species in the FRM filter, due to the inherent differences in the measurement techniques. To reconcile the expected differences between speciated and FRM measurements, species are adjusted following the SANDWICH method,⁶ which is described in the U.S. EPA modeling guidance.⁷ This adjustment results in reduced nitrates (relative to the amount measured by routine speciation networks), higher mass associated with sulfates and nitrates (reflecting water included in gravimetric FRM measurements), and an estimate of organic carbonaceous mass, which is derived from the difference between FRM-measured PM_{2.5} and the sum of all components except measured organic carbon. EPA's mass balance method sets a ceiling for OC mass (OCM) to be 80 percent of the total PM_{2.5} mass. However, based on scientific literature on PM_{2.5} speciation data taken in the greater Los Angeles area,^{8,9} this ceiling was set as the 50 percent of PM_{2.5} FRM mass. EPA's guidance also sets a floor value for OCM to be the measured OC value. However, the sum of individual species measured from CSN is sometimes larger than the FRM mass. Under this condition, the measured OC as floor would erroneously exaggerate the OC fraction while reducing the other species, therefore, the OC floor was scaled by the ratio of FRM mass divided by the total CSN mass.

Directly measured ammonium (associated with nitrate and sulfate) at CSN stations, which is equivalent to particulate ammonium retained on FRM filters, was used for the speciation profiles. These measurements, however, were capped with fully neutralized ammonium, which is calculated as follows:

$$\text{Ammonium ceiling} = 0.375 \times \text{sulfate} + 0.29 \times \text{retained nitrate}$$

Additionally, particle water bound (PBW) should be estimated as sulfate and nitrate retained on FRM filters include water because ammonium sulfate and ammonium nitrate are hygroscopic. PBW was estimated using a polynomial regression equation fitted to the equilibrium model Aerosol Inorganic Matter (AIM) as a function of sulfate, nitrate, and ammonium concentrations (described above). Most of FRM monitors in the basin do not have a co-located CSN monitor. Thus, as recommended by EPA guidance, we interpolated the individual speciation components

from co-located CSN monitors to latitude and longitude of FRM monitors that do not have a co-located CSN monitor. Inverse Distance Squared Weights interpolation method was used. This method gives a particular monitor a weight inversely proportional with squared distance from a given point.

Figures II-5-18 through II-5-21 provide SANDWICH-applied species fractions for each CSN site and each quarter. OC and nitrate are the two most common species with OC comprising between 30% to 43% of total PM_{2.5} mass, and nitrate comprising between 13% to 22% of the total PM_{2.5} mass, depending on quarter and location. OC in general tends to be higher in Urban Receptor and San Fernando regions both during the 3rd quarter while nitrate is the lowest during the same quarter. Higher temperatures and abundant sunlight increase evaporative emissions of SOA precursors and increase photochemical processing of those precursors.

On average, secondary ammonium, nitrate and sulfate comprise between 30% to 48% of the total PM_{2.5} concentration and show strong seasonal variability (Figure II-5-22); the highest contribution levels occur in quarter 2, among the four CSN stations. High nitrate concentrations in the fall or winter are caused by the favorable formation of ammonium nitrate under cool temperatures, high humidity, and frequent nocturnal inversions; the CSN stations on the east side – Fontana and Riverside – have the highest nitrate levels. On the contrary, high summertime temperatures reduce concentrations of nitrate, which is relatively volatile. The higher values of sulfate typically occur under conditions of strong inversions and strong sea breeze transport toward inland areas, which is the characteristic of late spring and summer. In addition, heterogeneous formation of sulfate is favored by higher temperatures occurring in the summer. Higher temperatures with abundant afternoon sunlight and the persistence of morning fog and low clouds trigger – the marine boundary layer, both homogeneous and heterogeneous sulfate formation reactions to produce secondary sulfate. Higher temperatures and abundant sunlight increase evaporative emissions of SOA precursors and increase photochemical processing of those precursors.

Speciated base year annual design values at different stations are shown in Figure II-5-23. Figure II-5-24 through Figure II-5-30 show the base year quarterly DV for the four CSN sites along with the stations with the top three highest annual design value in the basin which includes Ontario Near-road (ONNR), Mira Loma (MRLM), and Compton (CMPT). Among all the stations in the basin, the highest base year annual design value is observed at ONNR with an annual DV of 13.98 $\mu\text{g}/\text{m}^3$, followed by MRLM with a DV of 13.52 $\mu\text{g}/\text{m}^3$. MRLM is the station with the highest quarterly DV in the basin, with quarter 4 quarterly average exceeding 16 $\mu\text{g}/\text{m}^3$. Among the four CSN stations, the highest sulfate concentration was observed in central Los Angeles (4.81 $\mu\text{g}/\text{m}^3$), while the highest concentration of nitrate occurred in Fontana (2.22 $\mu\text{g}/\text{m}^3$) followed by Rubidoux (2.19 $\mu\text{g}/\text{m}^3$); Rubidoux also has the highest ammonium concentrations (0.95 $\mu\text{g}/\text{m}^3$).

Future Annual PM_{2.5} air quality

PM_{2.5} annual concentrations projected for milestone years are shown in Figure II-5-31. Ontario Near Road is projected to remain as the design value site in 2025 and 2030. The annual design value for Ontario Near Road in the 2030 attainment scenario is projected to be 12.35 $\mu\text{g}/\text{m}^3$. All other areas will be in attainment of the federal annual standard (12 $\mu\text{g}/\text{m}^3$) by 2030 with the proposed PM strategy presented in Chapter 4 of this Plan. A demonstration of Ontario Near Road projection using a hybrid modeling approach is provided in Chapter 5 and in chapter 6 of this Appendix II. Applying the hybrid approach, Ontario Near Road is expected to have 11.59 $\mu\text{g}/\text{m}^3$ in 2030 with the controls proposed in this Plan. Tables II-5-4 through II-5-6 provide the projected future year PM_{2.5} annual design values speciated by PM_{2.5} components for 2025, 2030 baseline and 2030 attainment.

Unmonitored Area Analysis

U.S. EPA modeling guidance requires that the attainment demonstration include an analysis that confirms that all grid cells in the modeling domain meet the federal standard. This “unmonitored area analysis” is essential since speciation monitoring is conducted at a limited number of sites in the modeling domain. Variability in the species profiles at selected locations coupled with the differing responses to emissions control scenarios are expected to result in spatially variable impacts to PM2.5 air quality in any grid cell. As described earlier in this chapter, speciation profiles from CSN sites are interpolated using inverse distance squared weighting. With interpolation of the CSN speciation profiles, attainment demonstrations can be directly conducted for the remaining grid cells where FRM mass data has been collected over the modified 5-year weighted period of 2016-2019.

The methodology used to assess the unmonitored grid cell impact is as follows. The speciation fractions throughout the Basin for each relevant species except particle bound water were estimated with inverse distance squared interpolation for each quarter of 2018. In the unmonitored area analysis, the modified five-year weighted annual PM2.5 design values were calculated for all Federal Reference Method (FRM) monitoring stations within the modelling domain for the 2016 to 2019 period for each quarter. Quarterly design values were interpolated using inverse distance squared weighting interpolation. The product of the interpolated total PM2.5 mass from the FRM monitors and the interpolated speciation fractions from the CSN monitors yields spatial distributions of speciated mass in each quarter. In order to maintain consistency with the attainment demonstration at individual stations, base and future year species concentrations at each grid cell were replaced with the average value of the 3x3 grid encompassing the selected grid cell. Model derived base and future-year quarterly averaged species concentrations were used to calculate RRFs for each species except water. RRFs were multiplied by quarterly averaged species concentrations to project future species concentrations. Particle-bound water was then calculated using a polynomial regression of the Aerosol Inorganic Model (AIM) and summed along with a “blank” concentration to calculate the quarterly-averaged PM2.5 future-year design values. Quarterly PM2.5 concentrations were averaged to produce future-year design values throughout the Basin. This approach is consistent with the U.S. EPA’s guidance.¹⁰

Figure II-5-32 shows the annual PM2.5 design values in the base year 2018 for the entire basin. Figures II-5-33 through II-5-35 provide the Basin-wide spatial extent of annual PM2.5 projected for 2025 baseline, 2030 baseline and 2030 attainment scenario. Without additional controls in the baseline 2025 and 2030, the number of grid cells with concentrations exceeding the federal standard is restricted to a small region around the Ontario CA-60 near-road and the Mira Loma monitoring stations, across the border between northwestern Riverside County and southwestern San Bernardino County. Figure II-5-35 shows the projected PM2.5 concentrations in 2030 with the full implementation of the PM2.5 control strategy, and

Summary and Conclusions

This section presents the performance of the modeling platform developed for this Draft-PM_{2.5} plan and demonstrates the attainment of the annual PM_{2.5} standard in 2030 in the South Coast Air Basin. The modeling platform reproduces the PM_{2.5} temporal trends throughout the year 2018 and shows good agreement with PM_{2.5} speciation. The control strategy presented in this Draft-PM_{2.5} plan is expected to lead the South Coast Air Basin to attainment of the 2012 annual PM_{2.5} standard in 2030. This was demonstrated using a traditional photochemical-modeling-based approach recommended by U.S. EPA and an alternative hybrid approach for Ontario CA-60 near-road site, which was developed in consultation with U.S. EPA and CARB. The latter approach is presented in detail in the next chapter of this appendix.

Chapter 6

ATTAINMENT DEMONSTRATION FOR THE CA-60 NEAR-ROAD MONITORING STATION

Introduction

Approach to Model the Effect of Near-Road Sources

AERMOD Dispersion Modeling Set-Up

PM2.5 simulation with AERMOD

Model Evaluation of Hybrid Model

Annual PM2.5 Design Values using the Hybrid Approach

Summary

Introduction

The current design site in the basin is the near-road monitor located by CA-60 freeway in Ontario. The monitor is sited just 16 meters away from the freeway, as shown in Figure II-6-1, and is heavily influenced by the emissions released from vehicles as well as resuspended particles caused by moving traffic. The Ontario CA-60 near-road monitor (referred to as CA60NR hereinafter) has been operational since 2015, and since the monitor started collecting data, it has been the station with the highest annual average PM_{2.5} concentration in the basin. This monitor surpassed the concentrations at the previous design site in Mira Loma, which is located approximately 12 km eastward. However, the differences in annual PM_{2.5} concentrations between Mira Loma and CA60NR have narrowed since 2015 (see Figure 5-11 in Chapter 5). This trend can be attributed to the fact that emissions from on-road sources have decreased substantially more than all other sources in the basin, and as a result, PM_{2.5} concentrations at near-road monitors are decreasing faster than concentrations at regional monitors that represent air quality of wider areas.

FIGURE II-6-1

LOCATION OF THE ONTARIO CA-60 NEAR-ROAD MONITOR

Regional photochemical transport modeling is designed to calculate air quality that is representative at the grid resolution of the model. This attainment demonstration uses a model resolution of 4 km by 4 km grid, and thus, should model concentration at monitors that are representative of a similar area. Near-road sites are heavily impacted by near-road sources and thus are not representative of the overall grid. U.S. EPA's modeling guidance acknowledges that attainment demonstration at near-road sites may

require a different treatment compared to other monitors as is indicated in modeling guidance, Section 4.6:

“PM2.5 measurement data from monitors that are not representative of “area-wide” air quality, but rather of relatively unique micro-scale, or localized hot spot, or unique middle-scale impact sites, are not eligible for comparison to the annual PM2.5 NAAQS.”

“... numerous cases where local source contributions may not be dominant, but are a sizable contributor to total PM2.5 (~10- 30% of total annual average PM2.5). In these cases, a more refined analysis of the contribution of local primary PM2.5 sources to PM2.5 at the monitor(s) will help explain the causes of nonattainment at and near the monitor.”

And in section 6.0:

“There may be some areas for which the supplemental evidence is persuasive enough to support a conclusion that the area can expect to achieve timely attainment despite failing the modeled attainment test,...”

For monitors affected by localized sources like the CA60NR site, the U.S. EPA modeling guidance suggests additional modeling techniques that would support the attainment demonstration. These techniques include increasing model resolution to a finer grid and using dispersion modeling to assess the impact of primary PM2.5 emissions from near sources on the monitor:

“A grid model can be run at very high horizontal resolution (1 or 2 km or finer) or a Gaussian dispersion model can be used. Grid based models simulate chemical transformation and complex meteorological conditions, while dispersion models are generally more simplistic; being limited to a local scale, using Gaussian approximations with little or no chemistry. Therefore, while dispersion models may not be an appropriate tool for determining secondary PM2.5 or ozone concentrations, they work well for use in determining local primary PM2.5 impacts.”

This chapter describes the application of hybrid approach using a combination of regional photochemical grid modeling (CMAQ) and dispersion modeling (AERMOD) to show that the annual PM2.5 concentrations at the CA60NR monitor are projected to decline more steeply than what the regional model suggests. The overall approach is to use CMAQ to model the impact of all sources at the grid resolution used in the attainment demonstrations, and to use AERMOD to quantify the elevated PM2.5 concentrations resulting from the proximity of the monitor to the emissions from vehicle and road dust resuspension along the freeway.

Approach to Model the Effect of Near-Road Sources

As the modeling guidance suggests, regional modeling may not be sufficient to represent the air pollution dynamics at near-road monitors and dispersion models can be used to determine primary PM2.5 impacts from on-road sources. Figure II-6-2 depicts how near-road sources contribute to PM2.5 concentrations around the monitor compared to how a regional model would quantify the grid cell-average impacts from

near-road sources. While the measurements at the near-road monitor observe a large contribution from near-road sources, a regional model only observes those near-road impacts averaged over the entire area of the modeling grid cell, resulting in an overall smaller impact. Regional modeling using CMAQ represents the air quality resulting from the regional sources plus the grid cell-average impacts of the near-road sources, whereas dispersion modeling using AERMOD can resolve the steep gradients in PM_{2.5} impacts from near-road sources. Thus, the use of AERMOD is used to quantify the near-road increment portion of the impacts from near-road sources that are beyond the grid cell-average near-road impacts. Because of the proximity of the monitor to the freeway, it is reasonable to assume that the impacts on PM_{2.5} primarily result from direct PM_{2.5} emissions and that the near-road impacts on secondary PM_{2.5} are negligible.

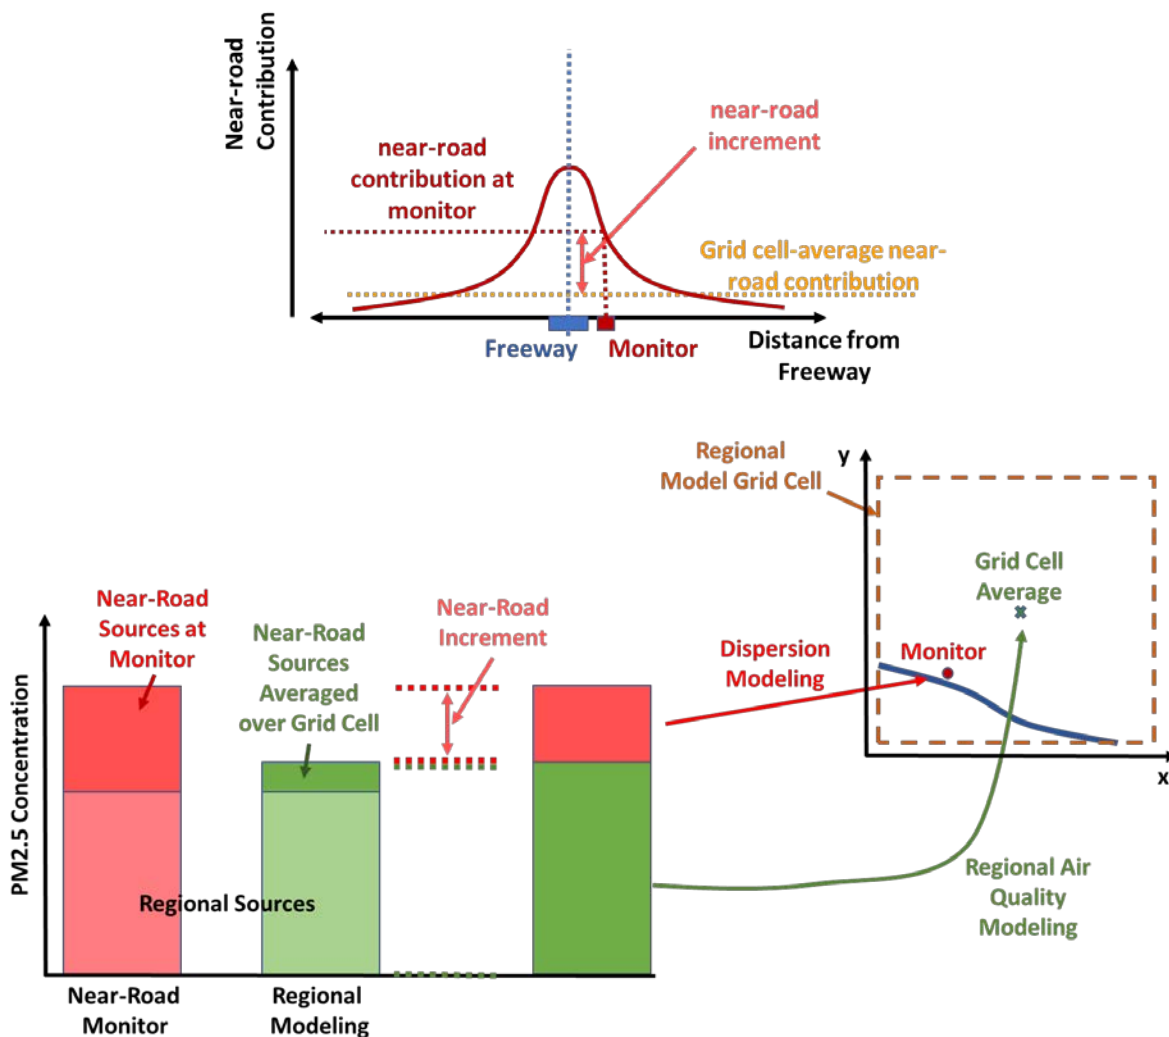

FIGURE II-6-2

SCHEMATICS OF THE HYBRID APPROACH TO INTEGRATE REGIONAL MODELING WITH DISPERSION MODELING OF NEAR-ROAD SOURCES

The receptor grid in the dispersion modeling setup spans the same area as the 4 km-by-4km regional modeling grid cell where the CA60NR monitor is located. The spacing of the receptors is 100 meters, with an additional receptor at the location of the monitor. The average of the concentrations at all receptors represents the receptor grid-average impact from near-road sources. The difference between the concentration at the CA60NR receptor monitor and the average across all dispersion modeling receptors is the AERMOD near-road increment (NRI_{AERMOD}):

$$C_{AERMOD,grid} = \frac{1}{N} \sum_{i=1}^N C_{AERMOD,i} \quad (II.6.1)$$

$$NRI_{AERMOD} = C_{AERMOD,CA60NR} - C_{AERMOD,grid} \quad (II.6.2)$$

where $C_{AERMOD,grid}$ is the near-road source contribution averaged over the AERMOD receptor grid, $C_{AERMOD,i}$ is the PM2.5 contribution at a given receptor i and N is the total number of receptors in the AERMOD modeling setup, and $C_{AERMOD,CA60NR}$ is the modeled near-road source contribution to PM2.5 concentration at the CA60NR monitor.

Alternatives for the determination of NRI

The magnitude of the NRI is a critical factor in the attainment demonstration for this near-road site. Because there are no speciated measurements at the CA60NR site, it is not possible to directly quantify the contribution of near-road sources to the overall PM2.5 measurements. Four potential approaches are considered to determine the NRI:

- 1) NRI based on AERMOD modeling, NRI_{AERMOD} , already described above.
- 2) NRI based on AERMOD for the monitor contribution, and CMAQ for the modeling grid cell average ($NRI_{AERMOD-CMAQ}$):

This approach is to calculate the NRI based on the concentrations calculated by AERMOD at the monitor and the near-road source contribution calculated using CMAQ at the CA60NR monitor cell. The calculation of the near-road source contribution to the CA60NR monitor cell ($C_{CMAQ,CA60NR}$) is calculated as follows:

$$C_{CMAQ,CA60NR} = C_{CMAQ,Base} - C_{CMAQ,NoCA60NR} \quad (II.6.3)$$

Where $C_{CMAQ,Base}$ is the PM2.5 concentration at the CA60NR monitor CMAQ grid cell in the base year simulation, and $C_{CMAQ,NoCA60NR}$ is the PM2.5 concentration in the simulation with all the base year emission sources included except for the near-road sources that are included in the AERMOD modeling setup. Then, this second alternative NRI, $NRI_{AERMOD-CMAQ}$, is calculated using the following expression:

$$NRI_{AERMOD-CMAQ} = C_{AERMOD,CA60NR} - C_{CMAQ,CA60NR} \quad (II.6.4)$$

This $NRI_{AERMOD-CMAQ}$ is used as the benchmark NRI, because the regional model (CMAQ) is the best tool available to determine the regional impacts from regional sources and which includes

secondary formation of PM_{2.5}, and dispersion modeling (AERMOD) is the best tool suited for short scale transport modeling typically used for source permitting.

3) NRI based on measured concentrations in nearby monitors:

As a third alternative, the NRI can be assessed by comparing PM_{2.5} levels at CA60NR with those at nearby monitoring stations. This approach was used in the attainment demonstration for annual PM_{2.5} in the Allegheny County, where there is a monitor that is in the vicinity of a large facility.¹ However, the case of CA60NR is different as there is not a single large facility affecting the monitor, but a collection of moving sources running along the CA-60 freeway. Three neighboring monitors, which are located within a 20-kilometer radius, are used in this approach: Mira Loma, Fontana and Rubidoux. It is important to note that the annual PM_{2.5} design value is calculated using speciated components of PM_{2.5}. However, neither the CA60NR monitor nor the closest monitors at Mira Loma and Fontana have speciated measurements available. Consequently, the speciation profile of the NRI is estimated based on dispersion modeling results. The NRI based on measured PM_{2.5} at neighboring sites, $NRI_{Monitors}$, is calculated as follows:

$$NRI_{Monitors} = DV_{CA60NR} - \frac{1}{N} \sum_{i=1}^N DV_i \quad (II.6.5)$$

Where DV_{CA60NR} is the design value observed at the CA60NR monitor, and DV_i is the design value observed at monitor i .

4) NRI based on the relative proportion of AERMOD and CMAQ modeled values ($NRI_{RelativeModel}$):

The fourth approach is to assume that the modeled $NRI_{AERMOD-CMAQ}$ and the regional sources modeled by CMAQ are in the same proportion as $(C_{CMAQ,Base})$ correspond to the monitored regional and local portions design value at the near-road monitor, DV_{CA60NR} . Then, the portion of the design value that corresponds to the near-road increment is defined by the ratio of the modeled $NRI_{AERMOD-CMAQ}$ to the total modeled concentration. This approach implies that the performance of CMAQ modeling regional sources and the performance of AERMOD modeling near-road sources are comparable.

The expression to calculate the $NRI_{RelativeModel}$ is as follows:

$$NRI_{RelativeModel} = DV_{CA60NR} \cdot \frac{NRI_{AERMOD-CMAQ}}{(NRI_{AERMOD-CMAQ} + C_{CMAQ,Base})} \quad (II.6.6)$$

Each equation represents slightly different definitions of NRI. The four NRI approaches are later evaluated to establish uncertainty bounds for calculating future design values using hybrid modeling results.

¹ Revision to the Allegheny County Portion of the Pennsylvania State Implementation Plan. Attainment Demonstration for the Allegheny County, PA PM_{2.5} Nonattainment Area, 2012 NAAQS.

<https://www.regulations.gov/search?filter=EPA-R03-OAR-2020-0157>

The estimated NRI is then subtracted from the base year design value, and the remaining portion corresponds to the contribution of all regional sources plus the grid cell average contribution of the near-road sources. This second portion of the DV is referred as the regional component of the DV (RDV):

$$RDV = (\text{Base Year DV}) - \text{NRI} \quad (\text{II.6.7})$$

Once the NRI and RDV components are disaggregated from the measured design value, future design value can be estimated by applying two differentiated Relative Reduction Factors (RRF) to these two components. The RDV component is projected using the RRF calculated from regional air quality modeling (RRF_{CMAQ}), and the NRI is projected using the RRF calculated using the dispersion modeling results (RRF_{AERMOD}). Figure II-6-3 illustrates this procedure. The resulting future year design value is calculated as follows:

$$\text{Future DV} = RDV * RRF_{CMAQ} + \text{NRI} * RRF_{AERMOD} \quad (\text{II.6.8})$$

It is important to note that dispersion modeling is used to estimate the NRI, which is an increment from what the regional modeling simulates. Thus, the regional modeling set-up includes all near-road sources, to account for the grid cell average component of near-road sources. Conversely, the receptor grid-average obtained from AERMOD is subtracted from the concentrations estimated by AERMOD at the monitor site, to calculate the NRI_{AERMOD} and avoid double counting of the grid cell average impacts from near-road sources. This approach is described in a 5-step process below.

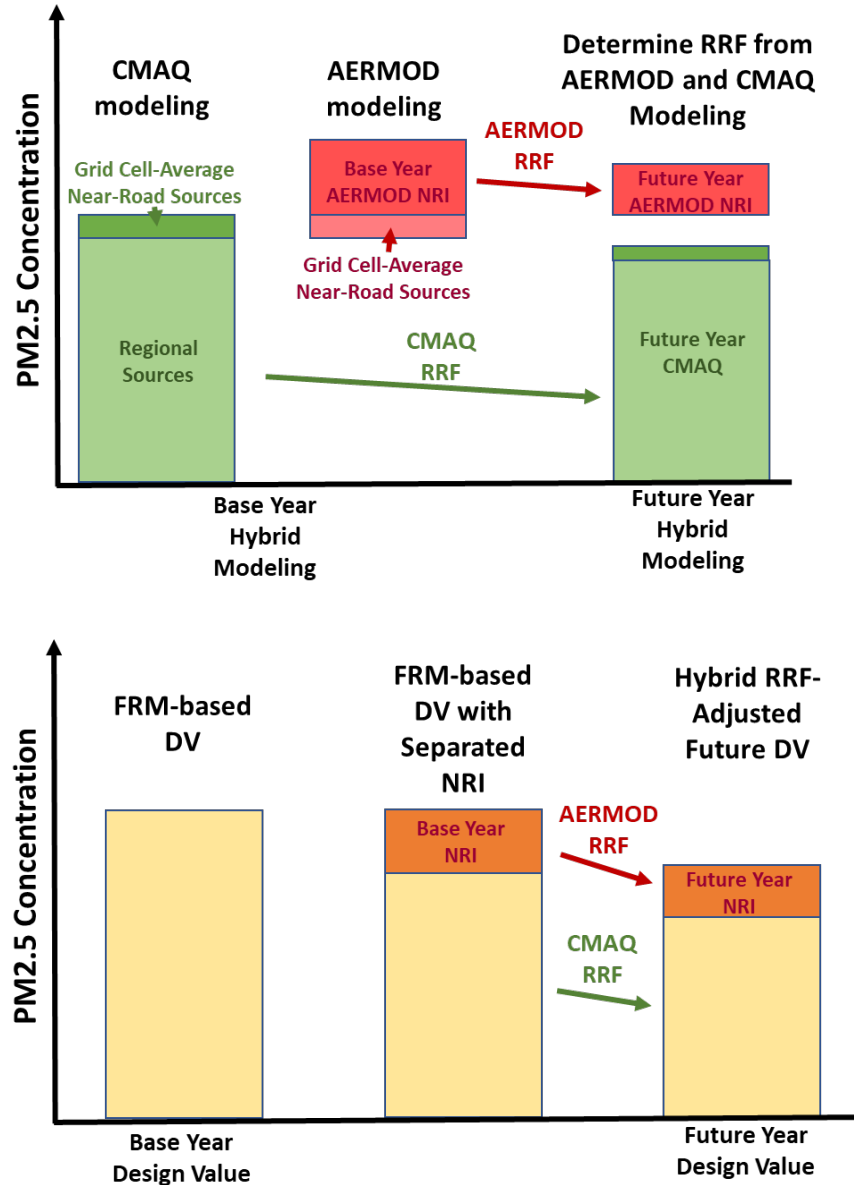

FIGURE II-6-3

DIAGRAM OF THE APPROACH TO PROJECT FUTURE PM_{2.5} CONCENTRATIONS USING RRF FOR REGIONAL MODELING AND DISPERSION MODELING OF NEAR-ROAD SOURCES

STEP 1: Conduct AERMOD dispersion modeling to determine the base year and attainment year speciated near-road increment.

The AERMOD modeling set-up is described in detail in the following section. The quarterly average contribution from near-road sources and the NRI_{AERMOD} for the base year is presented in Table II-6-1. Based on AERMOD modeling, the contribution from near-road sources averaged over the AERMOD receptor grid and averaged annually is $0.32 \mu\text{g}/\text{m}^3$, whereas the annual average contribution of near-road sources at the CA60NR monitor is $3.13 \mu\text{g}/\text{m}^3$. As a result, the estimated NRI_{AERMOD} annual average is $2.81 \mu\text{g}/\text{m}^3$. The future NRI and RRF calculated from the dispersion modeling are presented in Table II-6-2.

STEP 2: Determine the NRI.

As described above, we propose four alternatives to the calculation of NRI. Step 1 calculates the NRI_{AERMOD} used in the calculation of RRF_{AERMOD} .

The second alternative is to calculate the NRI using the grid cell-average near-road source contribution calculated with CMAQ. Two simulations are conducted to determine the contribution of near-road sources: (1) annual base year simulation with all emissions and (2) annual base year simulation that includes all emissions excluding the PM_{2.5} emissions from the near-road sources that are included in the AERMOD simulation. Then the difference in PM_{2.5} concentrations between the two simulations at the cell where CA60NR is located is the grid cell-average contribution of near-road sources, $C_{CMAQ,CA60NR}$. Then, the $NRI_{AERMOD-CMAQ}$ is calculated using equation II.6.4 using $C_{AERMOD,CA60NR}$ shown in Table II-6-1. The values for $C_{CMAQ,CA60NR}$ and $NRI_{AERMOD-CMAQ}$ are shown in Table II-6-3. The $NRI_{AERMOD-CMAQ}$ is larger than the NRI_{AERMOD} because the contribution from near-road sources estimated by CMAQ is smaller than the grid-cell average contribution calculated with AERMOD ($C_{AERMOD,grid}$).

*CMAQ estimated negative contribution to sulfate, nitrate, and ammonium, due to chemical interaction with organic aerosol precursors. Because AERMOD modeling only accounts for primary PM_{2.5}, negative values are capped at 0.

The third alternative for the NRI is calculated using monitoring data. There are 19 PM_{2.5} FRM monitoring stations in the basin, although only four stations measure speciated PM. The basin includes distinct geographical features and localized sources that causes PM_{2.5} concentrations vary widely throughout the region. Because of the wide range of sources and PM_{2.5} concentrations across the basin, the NRI in this attainment demonstration is estimated by using observations at the CA60NR and the three closest monitors: Mira Loma, Fontana, and Rubidoux. These three monitors are located within a 20-kilometer radius from CA60NR. Out of the four monitors, only Rubidoux measures speciated PM_{2.5}. Consequently, calculating speciated NRI is not possible from observations. Thus, the speciation of the NRI is based on the modeled speciated NRI using AERMOD. Table II-6-4 shows the quarterly average PM_{2.5} concentrations at the four monitors used to determine the NRI, the resulting NRI, and the quarterly speciation profiles calculated with AERMOD. The annual $NRI_{Monitors}$, estimated using monitoring data, is 1.64 $\mu\text{g}/\text{m}^3$, which is 45% less than the $NRI_{AERMOD-CMAQ}$. Both estimates are subject to uncertainties and there is no direct way to determine the accuracy of the estimates due to the lack of direct measurements.

The validity of $NRI_{Monitors}$ relies on the assumption that all the neighboring monitors are surrounded by the similar regional sources, and the only difference between CA60NR and all other monitors is the presence of freeway CA-60. However, a brief inspection of the surroundings of the neighboring monitors reveals that the monitor at Fontana is 1 km from Fontana's Auto Speedway racetrack and close to industrial yards, and the Mira Loma monitor is less than 2 km downwind from a large Union Pacific railyard and within 500 meters from a railroad. Thus, it is gross assumption that the difference in PM_{2.5} between CA60NR and the rest of neighboring monitors expressed by the $NRI_{Monitors}$ is due to the contribution from freeway CA-60 alone.

TABLE II-6-4

The fourth alternative is using the modeled NRI and CMAQ concentrations in relative terms to determine the portion of the design value that corresponds to the NRI, following equation II.6.6. The observed base year design value at the CA60NR monitor (DV_{CA60NR}) is shown in Table II-6-5. Equation II.6.6 requires the DV_{CA60NR} from Table II-6-5, the modeled concentrations by CMAQ at CA60NR shown in Table II-6-6 and the $NRI_{AERMOD-CMAQ}$ shown in Table II-6-3. The relative portion of PM_{2.5} species from $NRI_{AERMOD-CMAQ}$ with respect to total $NRI_{AERMOD-CMAQ}$ plus CMAQ concentrations, and the resulting $NRI_{RelativeModel}$ values are shown in Table II-6-6. The overall $NRI_{RelativeModel}$ is 1.80 $\mu\text{g}/\text{m}^3$, which is 40% less than the $NRI_{AERMOD-CMAQ}$, and slightly higher than the $NRI_{Monitors}$. As discussed earlier, because of the lack of direct speciated measurements at the CA60NR monitor, it is not possible to ascertain which of the four alternatives to the NRI is the most accurate. However, the range of values for NRI can provide a sense of uncertainty bounds in the modeling of future design values at the CA60NR.

In summary, the four alternatives described above span the range of NRI from 1.64 µg/m³ to 2.98 µg/m³. While there are no direct measurements or any comprehensive study near the CA60NR that could provide a better estimate of the contribution of near-road sources to observed PM_{2.5}, a recent study collected PM_{2.5} filter samples near two other southern California highways (I-5 and I-710), placing the samplers both upwind and downwind from the freeways.² Measurements over two weeks showed overall differences between upwind and downwind measurements ranging from 1 µg/m³ to 3 µg/m³, which are in the same range as the four alternatives for NRI.

STEP 3: Separate the NRI portion from the measured quarterly base year design value.

The quarterly averages of the base year design value are calculated following the methodology described in the U.S. EPA modeling guidance. Speciation at CA60NR is derived by interpolating the speciation profiles from the four CSN monitors in the basin. Then, the NRI is subtracted from the speciated base year design value to obtain RDV. In this example, *NRI_{AERMOD-CMAQ}* is used, and the breakdown between NRI and RDV is shown in Table II-6-7. Note that the estimated NRI for crustal component Other is larger than the estimated portion from the calculated base year design value in quarters 2 and 3. Thus, the values for Other in *NRI_{AERMOD-CMAQ}* in quarter 2 and quarter 3 are capped at the magnitude in the base year design value.

STEP 4: Project future DV by applying AERMOD-based RRF to NRI and CMAQ-based RRF to the regional component RDV.

The AERMOD-based RRF is calculated in Step 1 and is presented in Table II-6-2. The CMAQ-based RRF is calculated following the same methodology used in the traditional attainment demonstration approach, as described in the U.S. EPA modeling guidance. Namely, the quarterly average of modeled concentrations for the base year and the attainment scenario are averaged over a 3-by-3 grid centered at the grid cell where the monitor is located. The quarterly average value for each PM2.5 species in the attainment case divided by the quarterly average for the base year is the RRF for each PM2.5 species. The calculated RRF values are shown in Table II-6-8.

STEP 5: Add the future NRI and RDV components, calculate particle bound water and add blank to determine the future design value.

The future NRI and RDV components calculated in step 4 are added. Particle bound water is calculated following U.S. EPA modeling guidance, using a polynomial regression equation fitted to the equilibrium model Aerosol Inorganic Matter (AIM) as a function of sulfate, nitrate, and ammonium concentrations. The standard blank of $0.2 \mu\text{g}/\text{m}^3$ is added to the sum of all components to obtain the quarterly averages. The future annual design value is calculated as the average of the quarterly values. Table II-6-10 shows the calculated values, showing that the annual design value is $11.59 \mu\text{g}/\text{m}^3$, and thus demonstrating attainment of the annual PM_{2.5} standard.

TABLE II-6-10

The future design value calculated using this hybrid approach is sensitive to the magnitude of NRI. Because emissions from on-road sources are expected to decline faster than the overall emissions in the basin, the NRI portion is projected to decline faster than the RDV. Table II-6-11 shows the future design value calculated using $NRI_{Monitors}$, which the smallest among the four alternative NRI values. Since the magnitude of $NRI_{Monitors}$ is smaller than $NRI_{AERMOD-CMAQ}$, the overall future DV increases. As a result, the DV calculated using $NRI_{Monitors}$ is $11.91 \mu\text{g}/\text{m}^3$, higher than the DV calculated using $NRI_{AERMOD-CMAQ}$. Even though the DV calculated with a more conservative estimate of NRI is higher, this hybrid modeling approach demonstrates attainment of the annual PM_{2.5} standard.

AERMOD Dispersion Modeling Set-Up

The dispersion modeling set-up is based on the American Meteorological society (AMS) and U.S. EPA Regulatory Model–AERMOD (Cimorelli et al., 2005)³. AERMOD is one of the official EPA dispersion models required to be used for State Implementation Plan (SIP) revisions for existing sources and for New Source Review (NSR) and Prevention of Significant Deterioration (PSD) programs (U.S. EPA, 2017⁴). It has been widely employed in environmental science and air quality management (e.g., Gibson et al., 2013,⁵ Rood 2014⁶).

AERMOD incorporates air dispersion based on planetary boundary layer turbulence structure and scaling concepts, including treatment of both surface and elevated sources, and both simple and complex terrain. The AERMOD modeling system consists of several key components, including (1) AERMET, a meteorological data preprocessor; (2) AERMAP, a terrain data preprocessor that incorporates complex terrain using USGS Digital Elevation Data; (3) AERSCREEN, a screening version of AERMOD; (4) AERSURFACE, a surface characteristics preprocessor; and (5) BPIPPRIM, a multi-building dimensions program incorporating the GEP (Good Engineering Practice) technical procedures for PRIME (Plume Rise Model Enhancements) applications (U.S. EPA, 2017).

The meteorological data used in AERMOD to simulate the dispersion of pollutants was from the Weather Research and Forecasting (WRF) model version 4.4.2, which was run at a spatial resolution of 4 km by 4 km. Extensive evaluation of the meteorological modeling performance is presented in Chapter 3 of Appendix II of this plan. The meteorological data was processed with Meteorological Model Input Formulator (MMIF) version 4.0, which prepares the data for input into AERMOD. The data was then further processed and adjusted by the AERMET preprocessor to prepare the meteorological data specifically for AERMOD. Mixing heights, which are crucial for the vertical dispersion of air pollutants, were calculated by AERMET. AERMET was run with the Bulk Richardson number option to estimate the

vertical mixing height and it was configured to adjust the friction velocity (u^*) but without any wind direction randomization.

AERMAP was used to process terrain data. In the case of the Drat PM_{2.5} Plan, 1 arcsecond National Elevation Dataset (NED) was used as the terrain data. Receptors are points where pollutant concentrations are calculated to assess the impact of emissions. In this setup, receptors were placed at 100-meter intervals over one CMAQ grid (4 km by 4 km). Additionally, there was one discrete receptor located at the CA60NR monitor. The receptors were positioned at a height of 4.9 meters above the ground, which matches the probe height of the CA60NR monitor. This ensures consistency in the measurements. Figure II-6-4 shows the receptor grid and location of CA60NR.

The modeling emission set-up only includes the emission sources along freeway CA-60 and its on- and off-ramps. Emission sources are grouped into 10 groups so that each category is modeled using distinctive emissions temporal and chemical profiles that can be tracked throughout the modeling. These emissions are derived from SCAG's vehicle activity dataset, which is also used in the regional modeling set-up. SCAG's dataset includes vehicle activity for 5 different vehicle classes: light and medium duty vehicles, light heavy-duty trucks, medium heavy-duty trucks, heavy heavy-duty trucks, and buses. EMFAC 2021 is used to calculate an aggregated emissions factor on a per-mile basis for these 5 groupings that includes exhaust, and tire and brake wear emissions. In addition, road dust emissions are estimated by using SCAG's vehicle activity and road information dataset and by using the road dust methodology described in Attachment H of Appendix III from the 2022 AQMP. In total, five vehicle categories and two emission processes per vehicle class for a total of ten sources of emissions. Figure II-6-5 shows the distribution of the primary PM_{2.5} emissions along the freeway CA-60 within the dispersion modeling domain.

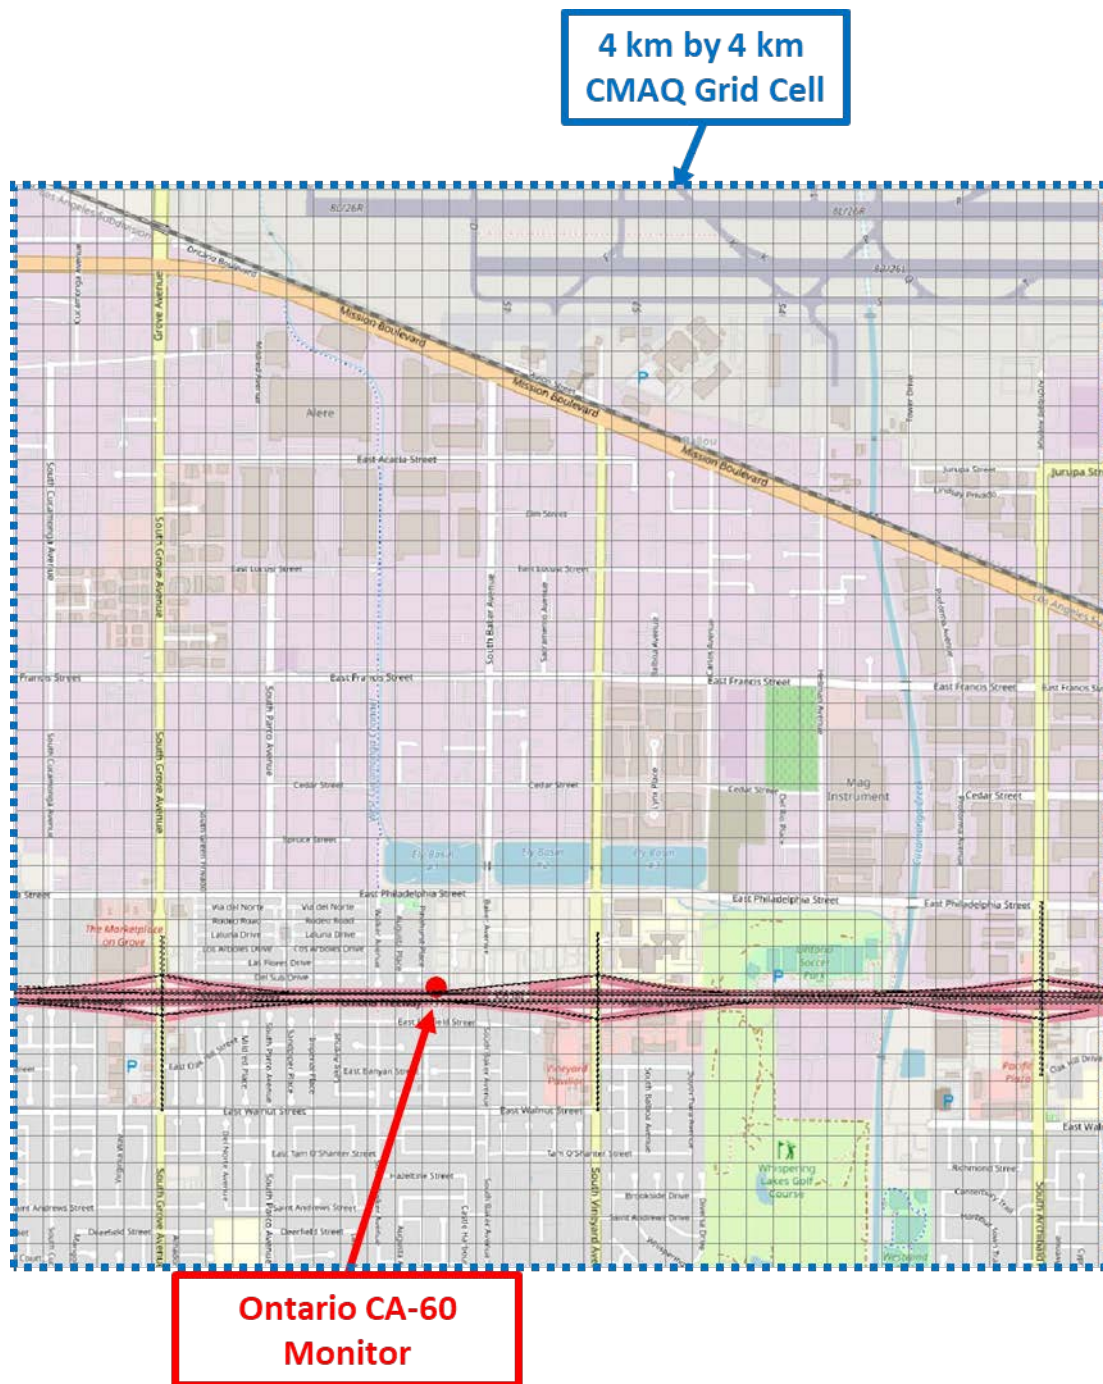

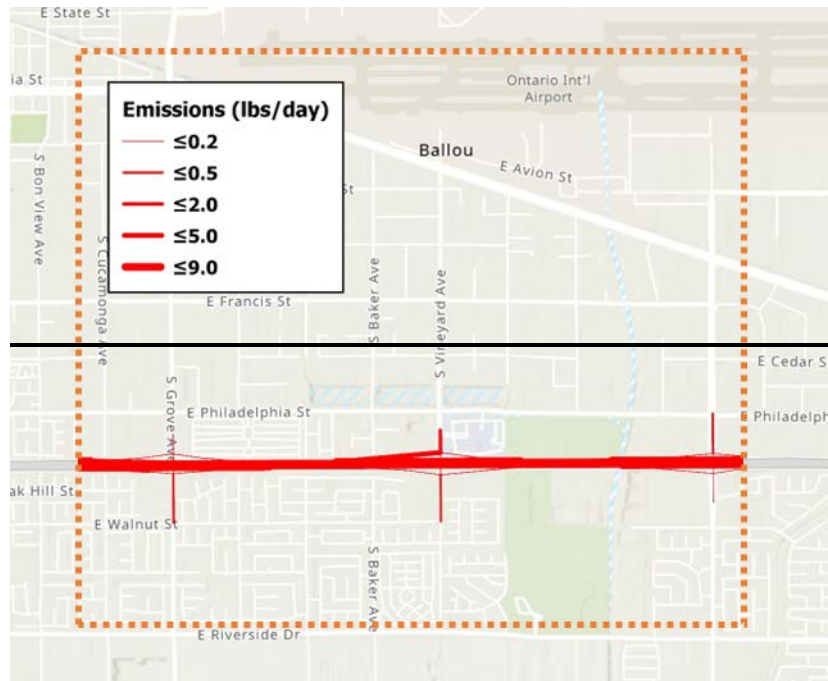

FIGURE II-6-4

DISPERSION MODELING DOMAIN SET-UP

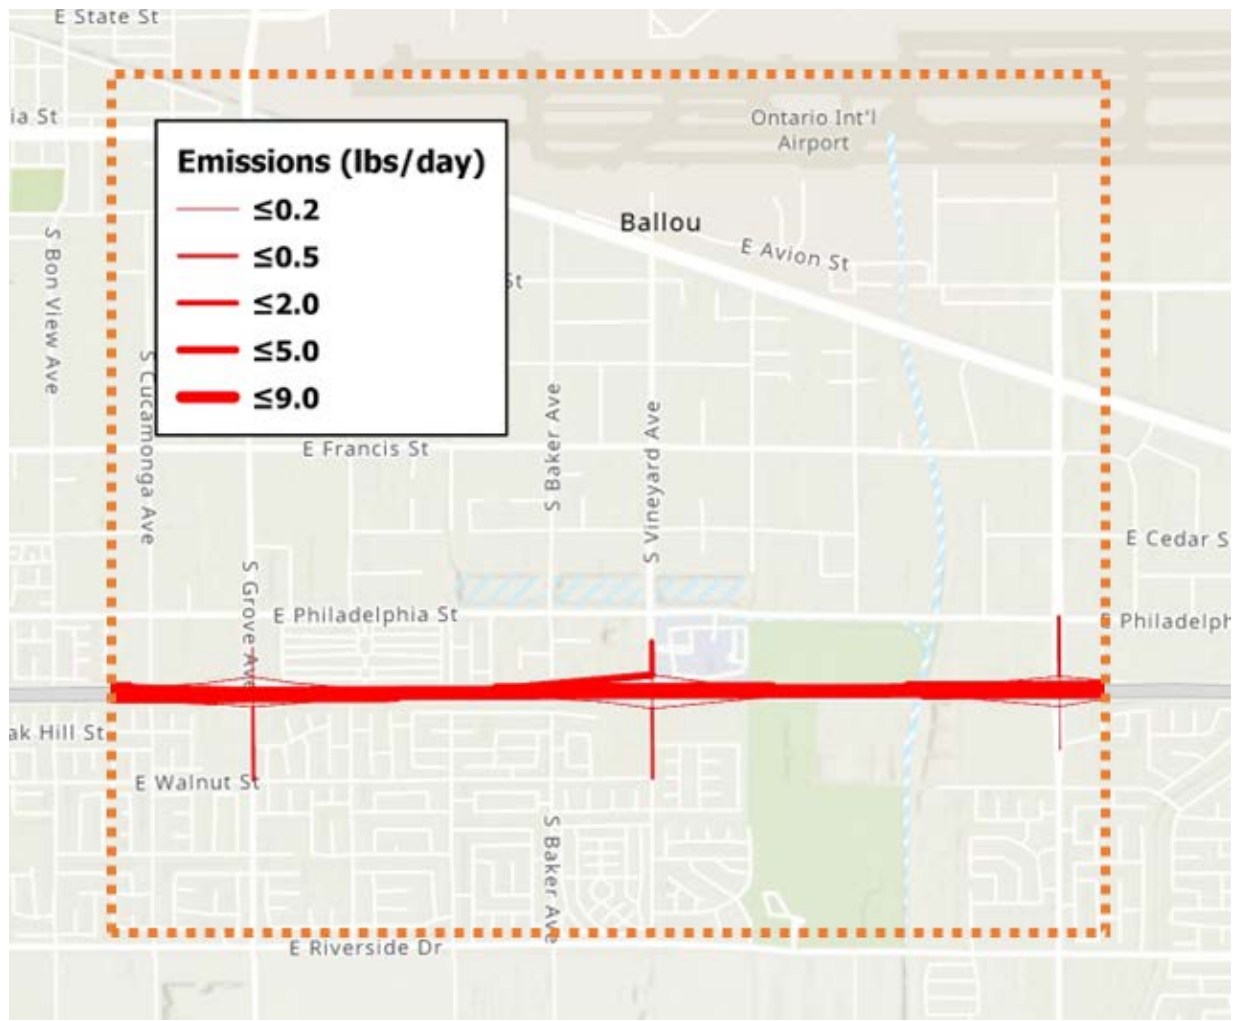

FIGURE II-6-5

SPATIAL DISTRIBUTION OF ON-ROAD PRIMARY PM_{2.5} EMISSIONS IN THE DISPERSION MODELING DOMAIN

Concentrations of total PM_{2.5} for all 10 emission sources are calculated on an hourly basis for the entire year of 2018. Daily emissions are calculated using average-day emission factors for the total PM_{2.5}. Temporal and chemical speciation profiles are applied as a post-processing step because both profiles are multipliers to the emissions. Because dispersion of pollutants is directly proportional to the emission flux, concentrations at different times and for different species are the product of the hourly estimated concentration and the temporal and chemical profile factors.

All emission sources were modeled as lines with constant emission rates. The initial vertical dimension for vehicle emissions was set at 5.1 meters, following examples from U.S. EPA's Conformity Hotspot

Guidance, Appendix J.3.⁷ The release height of vehicle emissions was set at 2.6 meters per the guidance suggestion, whereas road dust emissions release height was set at 0.5 meters above ground level. Hourly POST files (Post-Processing File) were generated for different source groups. These files contain detailed information about pollutant concentrations and dispersion patterns over time and space and are used for subsequent temporal scaling and analysis.

Table II-6-12 lists the annual average PM2.5 emissions from vehicle exhausts and paved road dust along the CA-60 freeway within the 4km-by-4km CMAQ model grid cell where the monitoring station is located. The total PM2.5 emissions from vehicle exhaust significantly drop from 39.31 lbs/day in the base year 2018 to 20.11 lbs/year in the 2030 attainment scenario primarily due to the adoption of cleaner vehicles. In contrast, PM2.5 emissions from paved-road dust slightly increase from 25.73 lbs/day in 2018 to 27.29 lbs/day in 2030 because of higher vehicle activity rates in the future.

TABLE II-6-12. ANNUAL AVERAGE PM2.5 EMISSIONS ALONG CA-60 FREEWAY IN THE DISPERSION MODELING DOMAIN

Source	Annual Average PM2.5 Emissions (pounds per day)	
	Base Year 2018	2030 Attainment
Road Dust

Total Emissions	65.0	47.4

⁷ PM Hot-spot Guidance. Transportation Conformity Guidance for Quantitative Hot-spot Analyses in PM2.5 and PM10 Nonattainment and Maintenance Areas, Office of Transportation and Air Quality, U.S. Environmental Protection Agency, EPA-420-B-21-037

Figure II-6-6 presents the mass fractions of primary PM_{2.5} speciation in the near-road emission sources. Speciation for vehicle emissions changes from 2018 to the 2030 attainment scenario, because exhaust emissions decline and tire and brake wear emissions become a relatively larger contributor to total vehicle emissions. As shown, crustal components (including primary particulates containing silicon, calcium, aluminum, iron, and titanium) dominate emissions from paved road dust, accounting for approximately 90% of the total mass of paved road dust emissions and contribute significantly to emissions from light-duty vehicles, accounting for approximately 50%. Following crustal components, organic carbon (OC) is the next significant contributor to light-duty vehicle emissions, accounting for over 25%. In heavy-duty vehicle emissions, elemental carbon (EC) is the largest contributor in 2018, followed by crustal components and OC. Because exhaust emissions from heavy-duty vehicles are substantially reduced in the future, the EC fraction declines substantially, and the tire and break wear contribution in the 2030 attainment becomes more prominent, increasing the crustal fraction.

FIGURE II-6-6

SPECIATION OF NEAR-ROAD EMISSION SOURCES

PM_{2.5} simulation with AERMOD

Figure II-6-7 shows the average PM_{2.5} concentration map calculated by AERMOD that represents the contribution of the direct PM_{2.5} emissions from on-road sources. The results indicate that the most significant impacts of on-road emissions are concentrated along the freeway near off-ramps, and the dispersion of PM_{2.5} is highly localized within a 300-meter radius from the freeway. Specifically, on-road

sources contribute $3.13 \mu\text{g}/\text{m}^3$ to PM_{2.5} levels at the monitoring site, while the average contribution across the entire 4 km-by-4 km grid cell is $0.32 \mu\text{g}/\text{m}^3$ (Figure II-6-8).

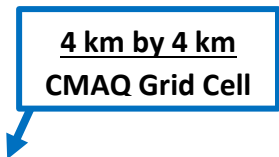

FIGURE II-6-7

ESTIMATES BASED ON DISPERSION MODELING OF THE CONTRIBUTION OF DIRECT PM_{2.5} EMISSIONS FROM CA-60 FREEWAY TO ANNUAL PM_{2.5} AROUND THE CA-60 NEAR ROAD MONITOR

Figure II-6-8 shows the contribution of on-road sources to annual PM_{2.5} at the monitoring station and as a grid-wide average across the 4 km-by-4 km grid cell where the monitor is located. The difference between the contribution at the monitor and the grid average contribution is the near-road increment calculated by AERMOD (NRI_{AERMOD}). The contribution is disaggregated by chemical components, showing that primary PM_{2.5} species are the dominant contributors. Crustal species are emitted largely from dust resuspension, whereas OC and EC are emitted from vehicle exhaust. Projections for the future year 2030 with the addition of emission controls targeting vehicle exhaust emissions are also shown in Figure II-6-8. Because of the introduction of cleaner vehicles in the future, the contribution of vehicle exhaust to OC and EC is substantially reduced by 2030. However, the contribution to crustal species, which is proportional to vehicle activities, increases slightly due to increased vehicle miles travelled (VMT) from 2018 through 2030.

FIGURE II-6-8

CONTRIBUTION OF DIRECT PM_{2.5} EMISSIONS ESTIMATED BY DISPERSION MODELING FROM CA-60 FREEWAY TO ANNUAL PM_{2.5} AT THE CA-60 NEAR-ROAD MONITOR AND GRID AVERAGE, FOR BASE YEAR 2018 AND FUTURE YEAR 2030 CONTROL SCENARIO

Model Evaluation of Hybrid Model

The use of the combination of regional modeling with CMAQ and local source dispersion modeling with AERMOD is motivated by the fact that the regional model CMAQ can only predict changes in concentrations averaged over a 4 km-by-4 km cell, whereas AERMOD can model the steep gradients in primary PM_{2.5} that occur between the freeway and the nearby monitor. As described above, AERMOD is used to determine the near-road increment in PM_{2.5} that is caused by the monitor being close to route CA60. To assess the performance of this hybrid approach, observations at the monitor are compared to hybrid modeling results (C_{Hybrid}) defined as the CMAQ modeled PM_{2.5} plus the NRI calculated with AERMOD:

$$C_{Hybrid} = C_{CMAQ,Base} + NRI_{AERMOD-CMAQ} \quad (II.6.9)$$

Equation II.6.9 is equivalent to the following expression:

$$C_{Hybrid} = C_{CMAQ,NoCA60NR} + C_{AERMOD,CA60NR} \quad (II.6.10)$$

Where $C_{CMAQ, NoCA60NR}$ is the modeled concentrations from the simulation with all the near-road source emissions included in the AERMOD setup removed from base year emissions. The difference between $C_{CMAQ, Base}$ and $C_{CMAQ, NoCA60NR}$ represents the contribution of near-road sources estimated by CMAQ, $C_{CMAQ, CA60NR}$. The annual average contribution from CA60NR near-road sources to total PM_{2.5} estimated by CMAQ is shown in Figure II-6-9. The impact of those sources is limited within the grid cells surrounding the CA60NR station and ranging from 0.01 to 0.15 $\mu\text{g}/\text{m}^3$.

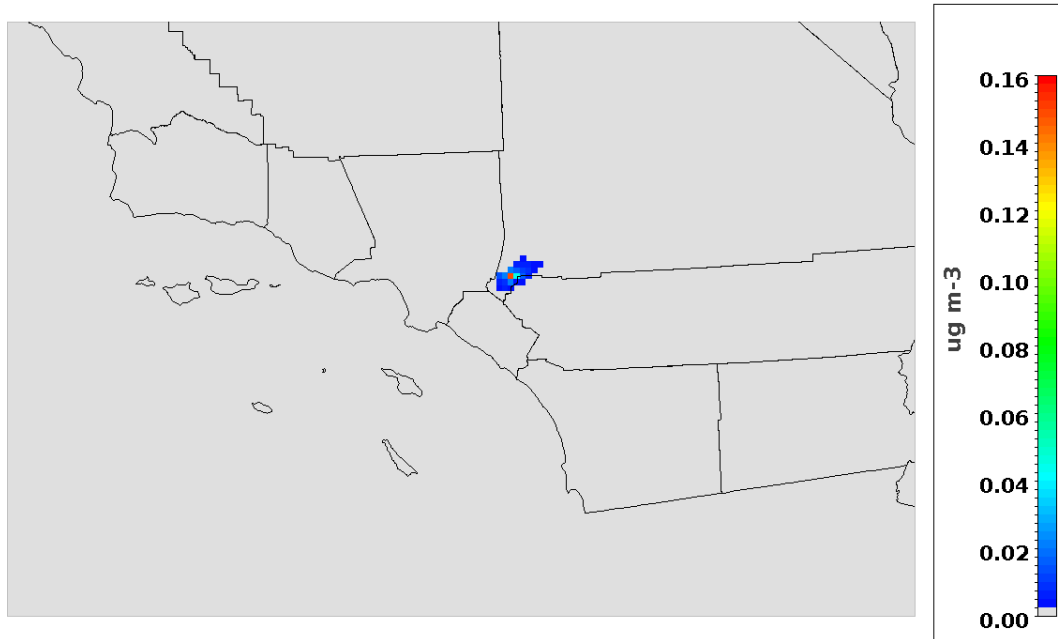

FIGURE II-6-9

CONTRIBUTION OF DIRECT PM_{2.5} EMISSIONS FROM NEAR-ROAD SOURCES AROUND CA60NR TO ANNUAL PM_{2.5} CONCENTRATIONS ESTIMATED BY CMAQ FOR BASE YEAR 2018

Figure II-6-10 shows the time series of daily PM_{2.5} comparing observations with modeled concentrations obtained with CMAQ and the hybrid modeling approach. In general, both CMAQ and the hybrid modeling approach capture the seasonal variation, showing higher concentrations in the first and fourth quarters of the month, and lower concentrations in spring and summer. Figure II-6-11 shows the daily near-road source contribution to CA60NR PM_{2.5} concentrations as modeled by AERMOD. As in the case of CMAQ modeling, PM_{2.5} concentrations modeled with AERMOD show higher peaks in the first and fourth quarters, due to stagnation that happens in colder months.

While seasonal trends are modeled reasonably well, the base CMAQ model overestimates PM_{2.5} concentrations, especially in the colder months. These biases may be attributed to biases in seasonal variations of emissions and/or mixing layer heights in the model. Because hybrid modeling adds approximately 3 $\mu\text{g}/\text{m}^3$ to the CMAQ base modeling to account for the contribution of the NRI, the hybrid modeling approach further overestimate PM_{2.5} concentrations, compared to CMAQ base modeling. As a

result, hybrid modeling shows higher bias and error than the CMAQ base modeling. However, CMAQ underestimates PM_{2.5} concentrations in spring and summer, and the hybrid modeling approach shows improvements by narrowing the gaps between modeling and observations during the spring and summer seasons. Table II-6-13 shows the modeling performance metrics for both CMAQ and the hybrid modeling approach. The metric definitions are included in Chapter 5 of Appendix II.

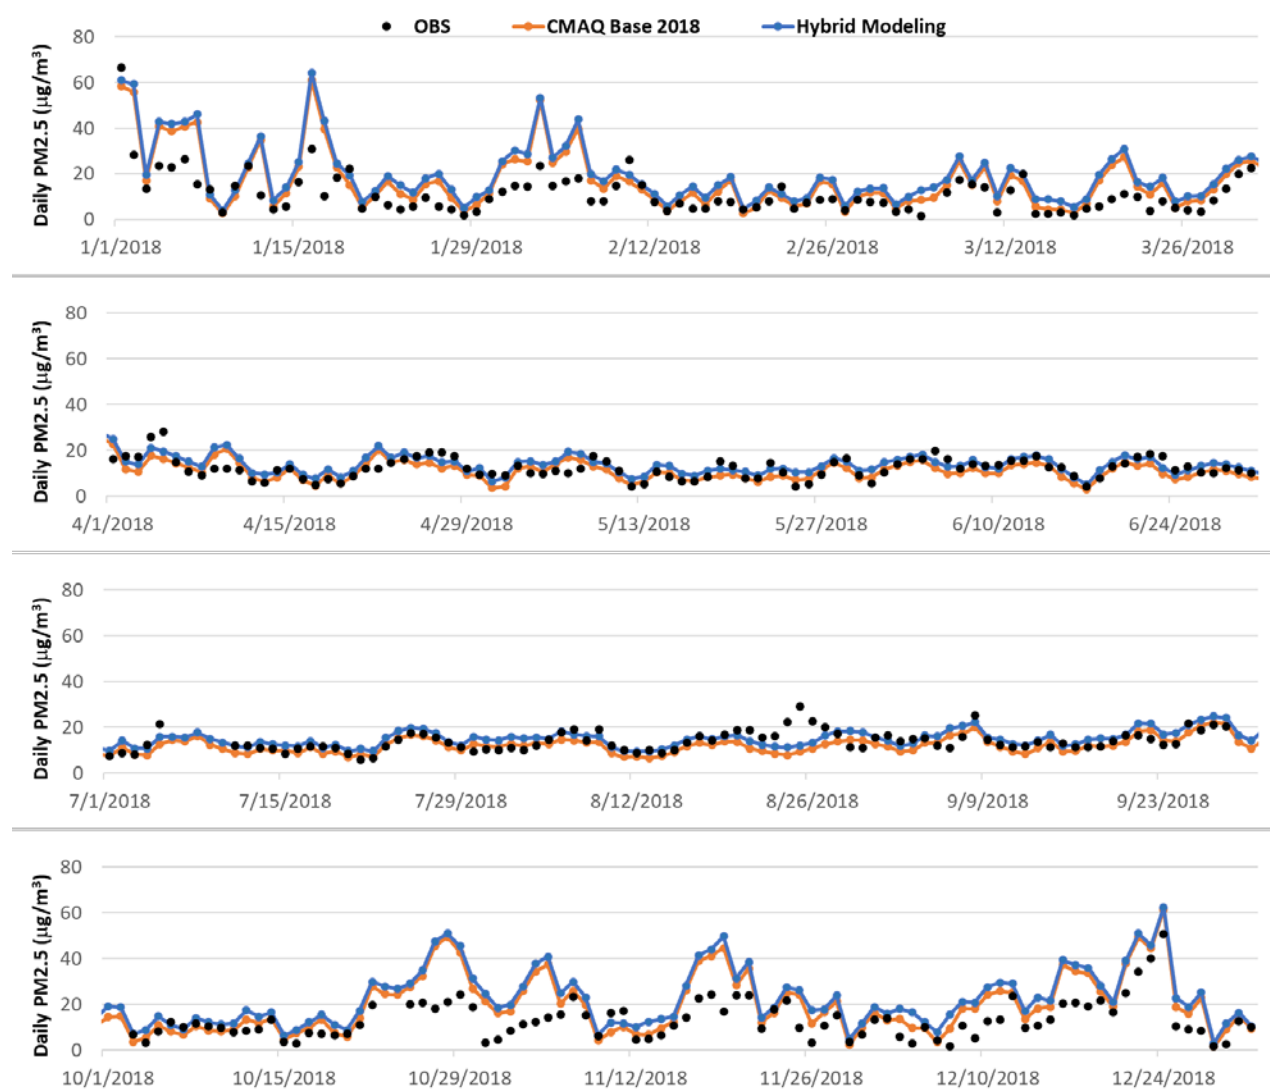

FIGURE II-6-10

Annual PM_{2.5} Design Values using the Hybrid Approach

The resulting future design values using the four different NRI estimates are compared to the DV calculated using the traditional approach and are shown in Figure II-6-12. While the traditional approach suggests that the CA-60 near-road monitor fails to attain the standard under the 2030 control scenario, the hybrid approach, designed to capture the steep gradients in direct PM_{2.5} concentrations around the freeway, shows that the projected annual PM_{2.5} concentration will be below the NAAQS of 12 $\mu\text{g}/\text{m}^3$. The hybrid approach using the $NRI_{\text{AERMOD-CMAQ}}$ based on AERMOD and CMAQ modeling projects the DV at 11.59 $\mu\text{g}/\text{m}^3$, demonstrating that CA60NR would meet the annual PM_{2.5} by a wide margin. The DV calculated using the NRI_{AERMOD} estimated purely from AERMOD modeling is projected to be 11.63 $\mu\text{g}/\text{m}^3$. The DV calculated using $NRI_{\text{RelativeModel}}$, based on combining both AERMOD and CMAQ modeling in relative terms to determine the NRI, is 11.75 $\mu\text{g}/\text{m}^3$. Even with the most conservative estimate of NRI based on monitoring data at neighboring sites, NRI_{Monitor} , the hybrid approach still shows that the DV at CA60NR would be 11.91 $\mu\text{g}/\text{m}^3$, well below the annual PM_{2.5} standard.

FIGURE II-6-12

COMPARISON OF DESIGN VALUE PROJECTIONS BETWEEN THE TRADITIONAL APPROACH AND THE HYBRID APPROACH USING DIFFERENT NRI ESTIMATES

Summary

The near-road monitoring site in Ontario (CA60NR) has recorded elevated PM_{2.5} levels since its data has been used for design value calculations in 2015. Annual PM_{2.5} concentrations at this near-road site consistently exceed those at the previous design site in Mira Loma, making CA60NR the new design site for annual PM_{2.5} in the South Coast Air Basin. However, accurately simulating PM_{2.5} and demonstrating potential future PM_{2.5} attainment at this near-road site are challenging due to substantial influence from nearby road-related sources and sub-grid scale spatial variation. This chapter focuses on the methodology and findings of PM_{2.5} attainment assessment at CA60NR by using a hybrid modeling system that combines a regional model (CMAQ) with a dispersion model (AERMOD). To address the unique challenges posed by near-road sites, a novel hybrid methodology is developed to quantify the contribution of PM_{2.5} emissions from vehicles and road dust to the near-road monitor's PM_{2.5} concentrations and to calculate the future annual PM_{2.5} design values using the hybrid approach. Results show that the hybrid approach estimates the future design value at the CA-60 near-road site is 11.59 µg/m³. Taking uncertainties into account to quantify the near-road increment, projections of design values at the Ontario CA-60 near-road site range between 11.59 and 11.91 µg/m³, and even with the most conservative NRI, the Ontario CA-60 near-road site is expected to attain the annual PM_{2.5} standard. This affirms that with the controls proposed in the Plan, all the locations including Ontario CA-60 near-road in the South Coast Air Basin will attain the 2012 annual PM_{2.5} NAAQS in 2030.

Conclusions

Introduction

The EPA Memorandum “Additional Methods, Determinations, and Analyses to Modify Air Quality Data Beyond Exceptional Events” (U.S. EPA, 2019)¹ published in 2019 establishes that ambient data that is not representative to characterize the base year design value may be excluded for the purposes of attainment demonstrations.

This report describes five 24-hour PM_{2.5} exceedances at the 60 Near Road monitor caused by Independence Day Fireworks that meet the exceptional event criteria established by the U.S. EPA (U.S. EPA, 2016²; U.S. EPA 2007³). The events occurred in the South Coast Air Basin, within the jurisdiction of the South Coast Air Quality Management District (South Coast AQMD). The table below shows a list of exceedances described in this report.

*Conc. = Concentration ($\mu\text{g}/\text{m}^3$)					

Emissions from the 4th and 5th of July fireworks lead to high PM_{2.5} concentrations region-wide. Exceedances occurred at other monitors throughout the South Coast Air Basin on the same days that the exceedances that occurred at the Route 60 Near Road station. While these exceedances also increased annual PM_{2.5} design values at these other monitors, exclusion of these exceedances would not result in a reduced carrying capacity.

Fireworks Emissions

Fireworks use is ubiquitous across Southern California on Independence Day. Many municipalities host professional fireworks displays on the evening of July 4th to commemorate the holiday. In addition, there is a strong culture of using personal-use “backyard” fireworks on Independence Day, which are likely the dominant source of fireworks emissions throughout the region based on video evidence from aerial observations. For example, see KCAL News, “Fourth of July: Residents celebrate America’s birthday with fireworks of their own”

<https://youtu.be/e08V6Sw0L4I>. Transcript of KCAL news story from July 4, 2023:

“Welcome back, I’m Suzie Suh. Now at 9:30, illegal fireworks going off all over the Southland, as you can see from our picture. Desmond Shaw is live in Skycal tonight, Desmond. Well Suzie, Happy 4th of July. I’ll put up the Map Tracker for a bit to show where we are. At the 405 and 710 right now, looking to north towards Lynwood, Compton, South L.A., and look at this in the distance. It almost looks like a giant lightning storm. Those are all fireworks almost exclusively from illegal variety here. It’s always so amazing to see this every year. Must be hundreds of thousands of pounds worth of illegal fireworks going off. I’m always reminded when LAPD or another agency discovers a big stash of fireworks that they haul offsite, it makes you wonder how many other stashes there must be out there to be able to ignite this many fireworks here. This has been going on for an hour; it’s going to be going on for at least another couple hours. And of course, this layer is getting so thick you can practically taste the gunpowder in the air. This will be with us into the early morning hours. So, unfortunate for our air quality. Very impressive to look at, but don’t forget that about 90% of this is not of the legal variety on this Independence Day evening. Live at Skycal overhead, I’m Desmond Shaw. Suzie, back to you in the studio”.

Personal-use fireworks are illegal in Ontario, CA, and several neighboring cities, see

Table II-7-2. Personal-use fireworks are also illegal in several upwind cities throughout the Basin including the City of Los Angeles, the largest city in the region with nearly 4 million residents. However, ordinances prohibiting the use of these fireworks are difficult to enforce. Data are not available to quantify the use of illegal fireworks in the city of Ontario, CA or upwind areas. However, the city of Ontario, CA held a takeback event in June 2021 encouraging citizens to turn in illegal fireworks with no questions asked and a house exploded in March of 2021 due to illegal fireworks <https://abc7.com/illegal-fireworks-ontario-takeback-explosion/10810827/>, which suggests that citizens might not always abide by the fireworks ban. Personal-use fireworks are widely available to purchase in cities that do allow fireworks.

* approximate distance

Professional Fireworks

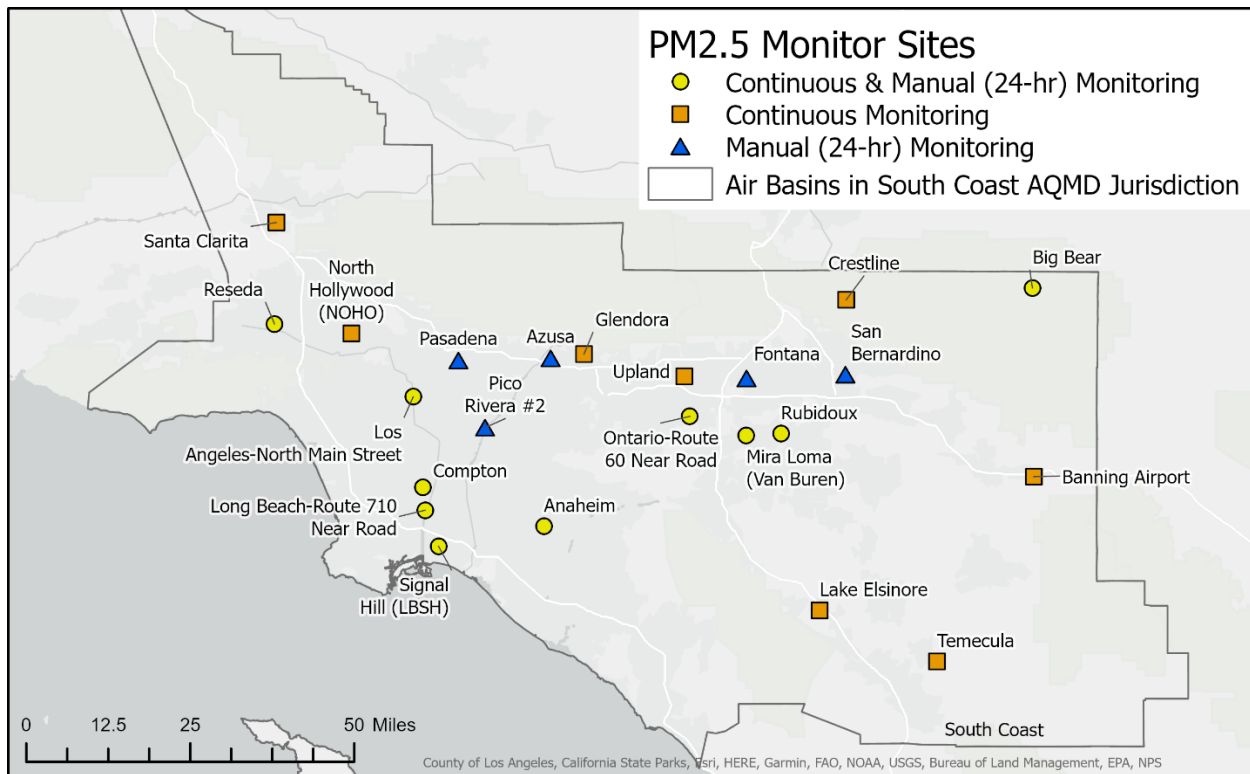

Table II-7-3 shows several examples of professional fireworks displays in Ontario, CA and neighboring cities planned for 2023 and in recent years. While we don't have complete records for professional grade fireworks events ~~for 2016–2019~~, such events are typically an annual event around July 4. The Fontana Herald News reported in June 2020 that Rancho Cucamonga would still launch fireworks despite no spectators being allowed to gather due to the COVID-19 pandemic, https://www.fontanaheraldnews.com/entertainment/rancho-cucamonga-will-have-fireworks-show-on-july-4/article_6eb09f5e-afec-11ea-b6cc-e325e7aee8a6.html. The article indicates that Rancho Cucamonga's fireworks typically occur at the LoanMart Field, which is located approximately 6.3 miles from the Ontario-Route 60 Near Road monitoring station. In addition to the professional fireworks displays near the monitoring station, professional fireworks displays are common throughout upwind areas in the Los Angeles metropolitan area.

Historical Analysis

Figure II-7-1 shows a map of the regulatory PM_{2.5} monitors in the South Coast Air Basin. Figure II-7-2 through Figure II-7-13 show historical data during the 3-month period centered on July 4 and 5 for 2015-2019 for the Ontario-Route 60 Near Road, Mira Loma (Van Buren), Rubidoux, Anaheim, and Los Angeles-North Main monitoring stations. Data from stations other than Ontario-Route 60 Near Road are included to demonstrate the regional nature of these events. The data are plotted as both time series and boxplots. The lengths of the whiskers in the boxplots indicate the 1st and 99th percentiles. The exceedances in Table 1 are all anomalously high; all of the five exceedance events at the Ontario-Route 60 Near Road monitor are squarely above the 99th percentile. Hazard Mapping System (HMS)⁴ and NASA Worldview were used to categorize the data as wildfire-impacted and non-wildfire impacted; the data were also categorized as July 4 or 5 and other days, leading to four groupings of data. Note that the data used to calculate the boxplots do not include any July 4 or 5 data. This set of figures demonstrate that across multiple years, exceedances during the summer predominantly occur on July 4 and July 5 or on days with evidence of wildfire impacts.

⁴ National Oceanic and Atmospheric Administration, Office of Satellite and Product Operations, National Environmental Satellite, Data, and Information Service. 2023. "Hazard Mapping System Fire and Smoke Product." <https://www.ospo.noaa.gov/Products/land/hms.html>.

Fireworks Summary for 2016-07-05

As is documented earlier in this report, the use of personal fireworks is widespread throughout the Basin. Since personal fireworks are predominantly used in residential neighborhoods, residential land use serves as a proxy for locations of fireworks emissions. Residential land use from the 2019 annual land use dataset from the Southern California Association of Governments (SCAG;

https://hub.scag.ca.gov/datasets/ea9fda878c1947d2afac5142fd5cb658_0/about) is shown in Figure II-7-14. Residential land use, along with mixed residential and commercial land use are shown in the map. HYSPLIT⁵ back-trajectories using the National Oceanic and Atmospheric Administration (NOAA) High Resolution Rapid Refresh (HRRR) 3km meteorological model arriving 50m above the 60 Near Road monitoring station for July 4-5, 2016 are also shown in

⁵ HYSPLIT Trajectories. 2023. NOAA Air Resources Laboratory. https://www.ready.noaa.gov/HYSPLIT_traj.php.

Figure II-7-14. All the back-trajectories originate over the Pacific Ocean and cross large residential areas of the South Coast Air Basin. Figure II-7-15 shows wind roses throughout the South Coast Air Basin for 9 PM on July 4 through 2 PM on July 5, 2016 using wind data from South Coast AQMD monitoring stations and local airports. The wind roses in Figure II-7-15 confirm the onshore wind pattern shown in the HYSPLIT back-trajectories in Figure II-7-14.

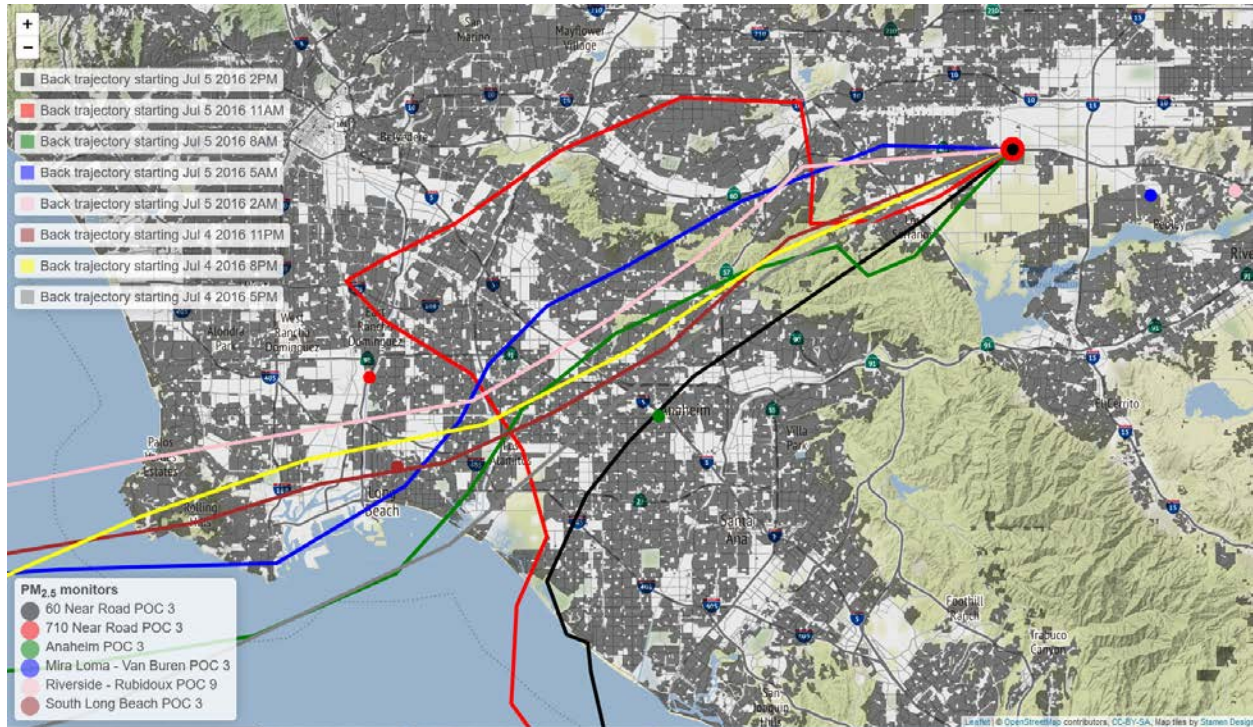

FIGURE II-7-14:
HYSPLIT BACK-TRAJECTORIES FROM 60 NEAR ROAD FOR JULY 4-5, 2016 OVERLAID ON A MAP OF THE SOUTH COAST AIR BASIN SHOWING RESIDENTIAL LAND USE (SHOWN IN GRAY).

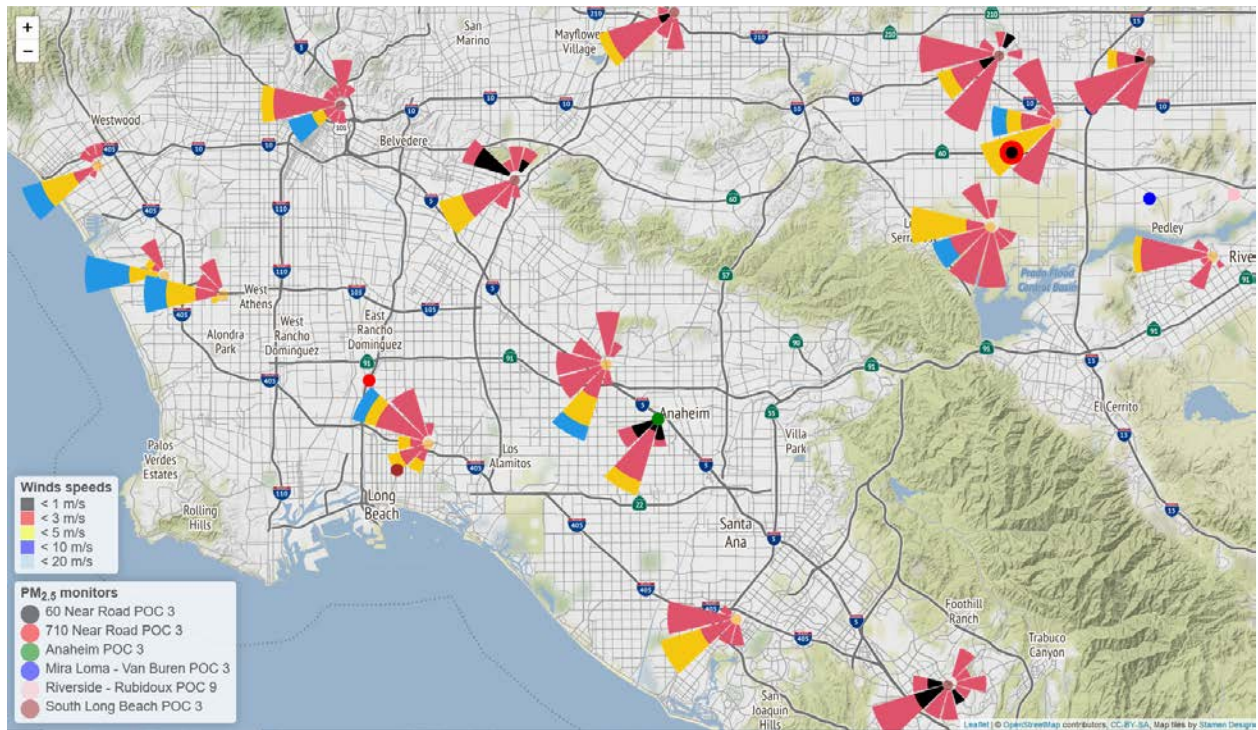

FIGURE II-7-15:
WIND ROSES FOR 9 PM ON JULY 4 THROUGH 2 PM ON JULY 5, 2016 THROUGHOUT THE SOUTH COAST AIR BASIN.

Figure II-7-16 shows time series plots of hourly PM_{2.5} data at selected stations with continuous PM_{2.5} instruments within the South Coast Air Basin for July 4-5, 2016. The concentrations peak

at stations closer to the coast earlier than in inland areas (see Figure II-7-14 for monitor locations). This is consistent with the combination of 1) extensive fireworks use across the Basin, especially the most populated areas closer to the coast and 2) the dominant onshore flow that transports these emissions inland. The inland areas have local emissions as well as transported emissions from upwind areas.

FIGURE II-7-16:
HOURLY TIME SERIES FOR JULY 4-5, 2016 FOR PM_{2.5} MONITORING STATIONS IN THE SOUTH COAST AIR BASIN.

Fireworks Summary for 2017-07-04 and 2017-07-05

Residential land use (a proxy for fireworks emissions locations) and HYSPLIT back-trajectories using the NOAA HRRR meteorological model arriving at the 60 Near Road monitoring station for July 4-5, 2017 are shown in Figure II-7-17. All the back-trajectories originate over the Pacific Ocean and cross large residential areas of the South Coast Air Basin. Figure II-7-18 shows wind roses throughout the South Coast Air Basin for 9 PM on July 4 through 2 PM on July 5, 2017 using wind data from South Coast AQMD monitoring stations and local airports. The wind roses in Figure II-7-18 confirm the onshore wind pattern shown in the HYSPLIT back-trajectories in Figure II-7-17.

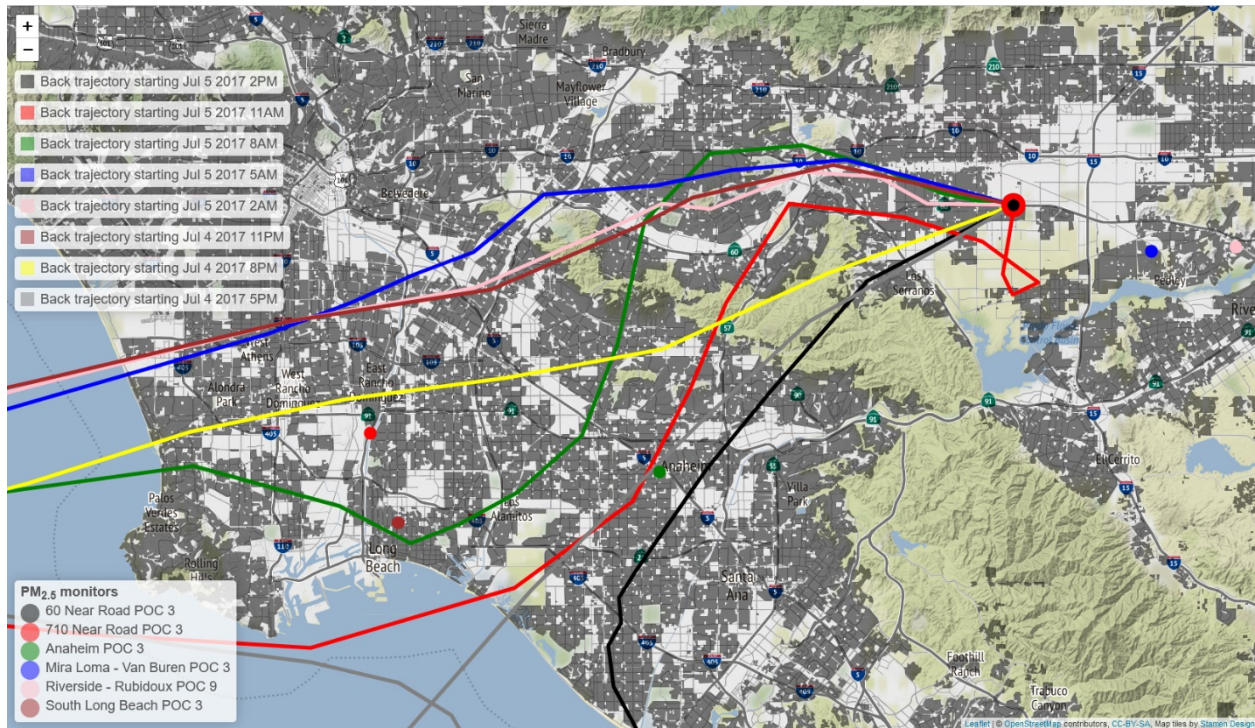

FIGURE II-7-17:
HYSPLIT BACK-TRAJECTORIES FROM 60 NEAR ROAD FOR JULY 4-5, 2017 OVERLAID ON A MAP OF THE SOUTH COAST AIR BASIN SHOWING RESIDENTIAL LAND USE (SHOWN IN GRAY).

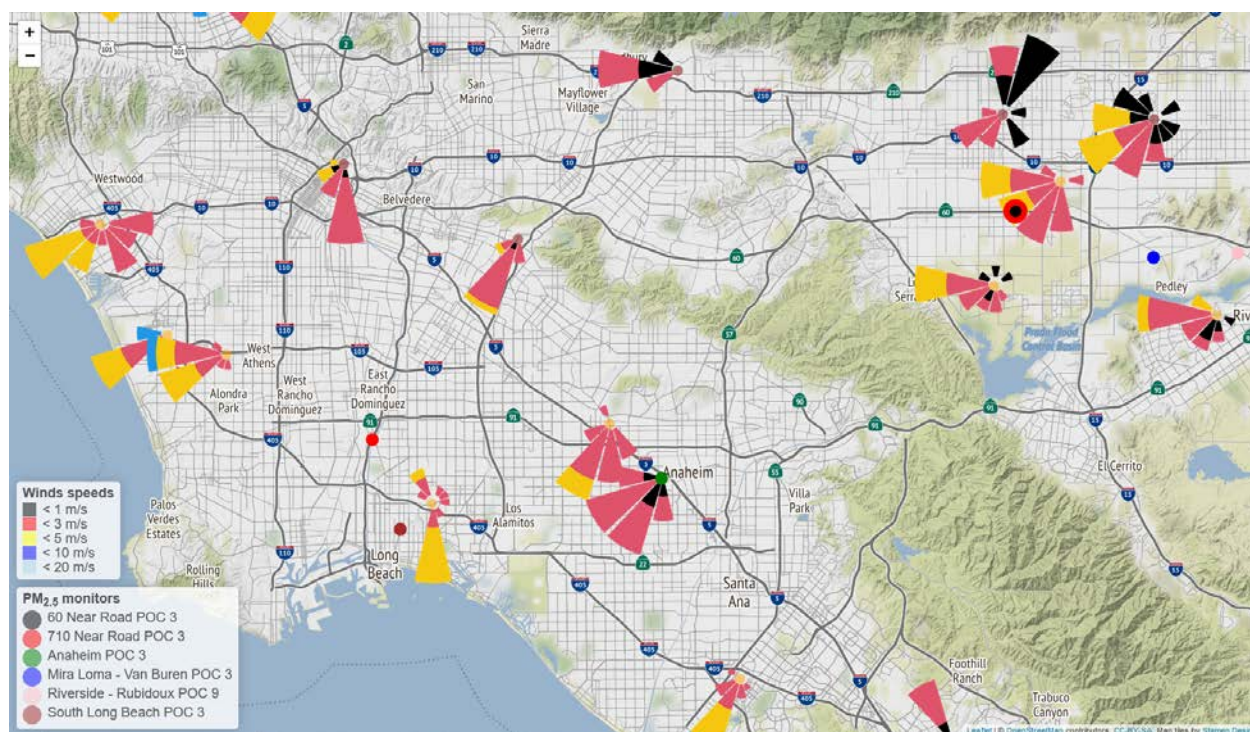

FIGURE II-7-18:
WIND ROSES FOR 9 PM ON JULY 4 THROUGH 2 PM ON JULY 5, 2017 THROUGHOUT THE SOUTH COAST AIR BASIN.

Figure II-7-19 shows time series plots of hourly PM_{2.5} data at selected stations with continuous PM_{2.5} instruments within the South Coast Air Basin for July 3-5, 2017. The concentrations peak at stations closer to the coast earlier than in inland areas (see Figure II-7-17 for monitor locations). This is consistent with the combination of 1) extensive fireworks use across the Basin, especially the most populated areas closer to the coast and 2) the dominant onshore flow that transports these emissions inland. The inland areas have local emissions as well as transported emissions from upwind areas.

**FIGURE II-7-19:
HOURLY TIME SERIES FOR JULY 3-5, 2017 FOR PM_{2.5} MONITORING STATIONS IN THE SOUTH
COAST AIR BASIN.**

Figure II-7-20 through Figure II-7-21 show time series plots of PM_{2.5} (left axes) and windspeed (right axes) for the stations shown in Figure II-7-19 that have co-located wind data. The PM_{2.5} concentrations tend to be the highest during the periods with lowest windspeeds. This is consistent with elevated nearby emissions, such as fireworks and reflects the emission patterns of fireworks, which are typically used at nightfall.

FIGURE II-7-20:
HOURLY PM2.5 AND WINDSPEED FOR JULY 3-5, 2017 AT THE RIVERSIDE - RUBIDOUX STATION.

**FIGURE II-7-21:
HOURLY PM_{2.5} AND WINDSPEED FOR JULY 3-5, 2017 AT THE ANAHEIM STATION.**

Figure II-7-22 through Figure II-7-23 show scatter plots of PM_{2.5} versus hourly windspeed. This is the same data as shown in Figure II-7-20 through Figure II-7-21, except that the data are limited to 9 PM on July 4 through 5 PM on July 5, 2017 when we expect the greatest impacts from fireworks emissions. The NAAQS value (35 µg/m³) is shown as a horizontal line. Most PM_{2.5} measurements were below the NAAQS value whenever the winds were above approximately 5 knots, with the highest concentrations occurring at lower wind speeds. This pattern is consistent with elevated nearby emissions from fireworks accumulating to high concentrations during periods of lower ventilation and then diluting during periods of increased ventilation at higher windspeeds.

FIGURE II-7-22:
HOURLY PM2.5 VERSUS WINDSPEED FOR 9 PM ON JULY 4 THROUGH 5 PM ON JULY 5, 2017
AT THE RIVERSIDE - RUBIDOUX STATION.

FIGURE II-7-23:
HOURLY PM_{2.5} VERSUS WINDSPEED FOR 9 PM ON JULY 4 THROUGH 5 PM ON JULY 5, 2017
AT THE ANAHEIM STATION.

Fireworks Summary for 2018-07-05

Residential land use (a proxy for fireworks emissions locations) and HYSPLIT back-trajectories using the NOAA HRRR meteorological model arriving at the 60 Near Road monitoring station for July 4-5, 2018 are shown in Figure II-7-24. All the back-trajectories originate over the Pacific Ocean or locally within the South Coast Air Basin and cross large residential areas of the South Coast Air Basin. Figure II-7-25 shows wind roses throughout the South Coast Air Basin for 9 PM on July 4 through 2 PM on July 5, 2018 using wind data from South Coast AQMD monitoring stations and local airports. The low windspeeds and onshore components shown in the wind roses in Figure II-7-25 are consistent with the meandering and ocean-sourced HYSPLIT back-trajectories in Figure II-7-24.

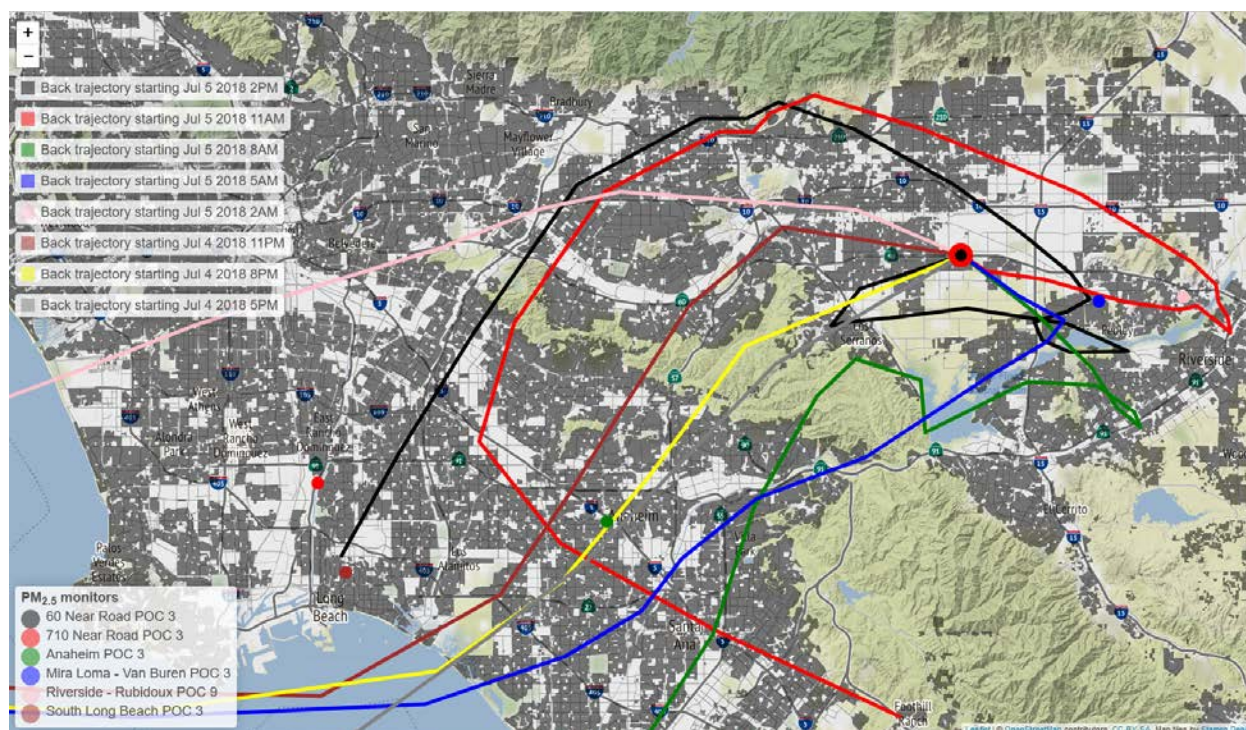

FIGURE II-7-24:
HYSPLIT BACK-TRAJECTORIES FROM 60 NEAR ROAD FOR JULY 4-5, 2018 OVERLAID ON A MAP
OF THE SOUTH COAST AIR BASIN SHOWING RESIDENTIAL LAND USE (SHOWN IN GRAY).

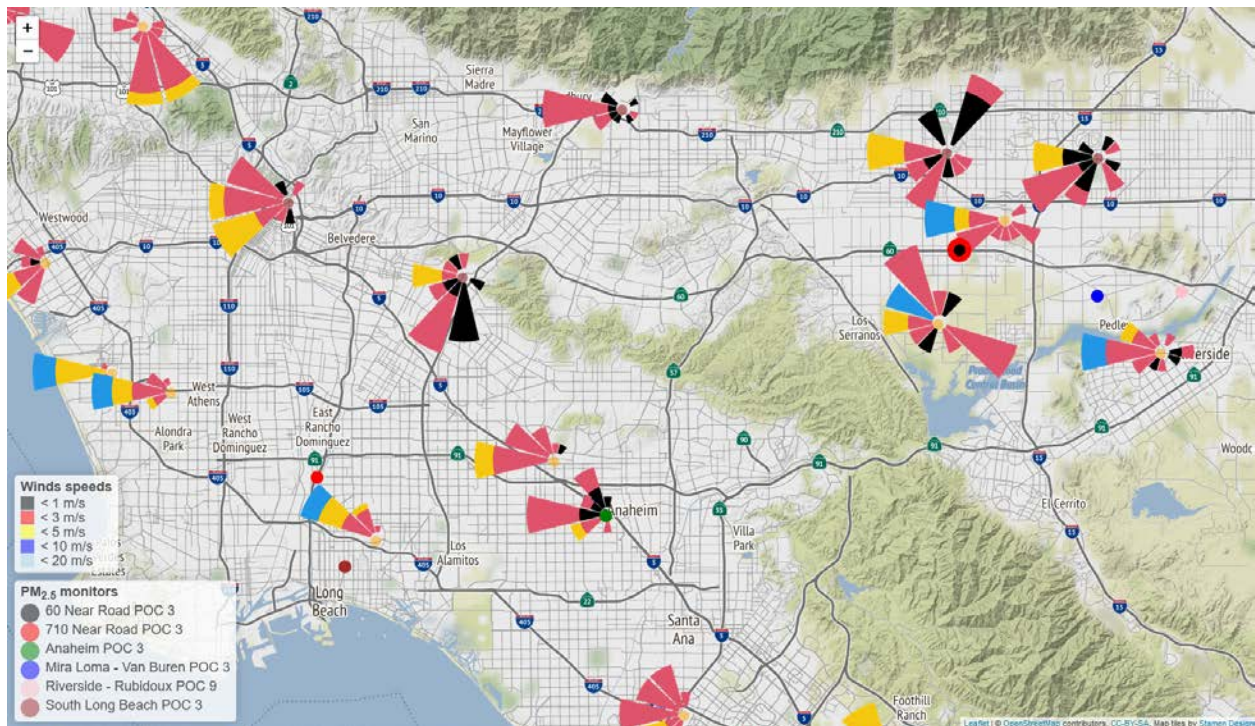

FIGURE II-7-25:
WIND ROSES FOR 9 PM ON JULY 4 THROUGH 2 PM ON JULY 5, 2018 THROUGHOUT THE SOUTH COAST AIR BASIN.

Figure II-7-26 shows time series plots of hourly PM_{2.5} data at selected stations with continuous PM_{2.5} instruments within the South Coast Air Basin for July 4-5, 2018. The concentrations peak at stations closer to the coast earlier than in inland areas (see Figure II-7-24 for monitor locations). This is consistent with the combination of 1) extensive fireworks use across the Basin, especially the most populated areas closer to the coast and 2) the dominant onshore flow that transports these emissions inland. The inland areas have local emissions as well as transported emissions from upwind areas.

FIGURE II-7-26:
HOURLY TIME SERIES FOR JULY 4-5, 2018 FOR PM_{2.5} MONITORING STATIONS IN THE SOUTH COAST AIR BASIN.

Figure II-7-27 through Figure II-7-29 show time series plots of PM_{2.5} (left axes) and windspeed (right axes) for the stations shown in Figure II-7-26 that have co-located wind data. The PM_{2.5} concentrations tend to be the highest during the periods with lowest windspeeds. This is consistent with elevated nearby emissions, such as fireworks and reflects the emission patterns of fireworks, which are typically used at nightfall.

Fireworks Summary for 2019-07-05

Residential land use (a proxy for fireworks emissions locations) and HYSPLIT back-trajectories using the NOAA HRRR meteorological model arriving at the 60 Near Road monitoring station for July 4-5, 2019 are shown in Figure II-7-33. All the back-trajectories originate over the Pacific Ocean and cross large residential areas of the South Coast Air Basin. Figure II-7-34 shows wind roses throughout the South Coast Air Basin for 9 PM on July 4 through 2 PM on July 5, 2019 using wind data from South Coast AQMD monitoring stations and local airports. The wind roses in Figure II-7-34 confirm the onshore wind pattern shown in the HYSPLIT back-trajectories in Figure II-7-33.

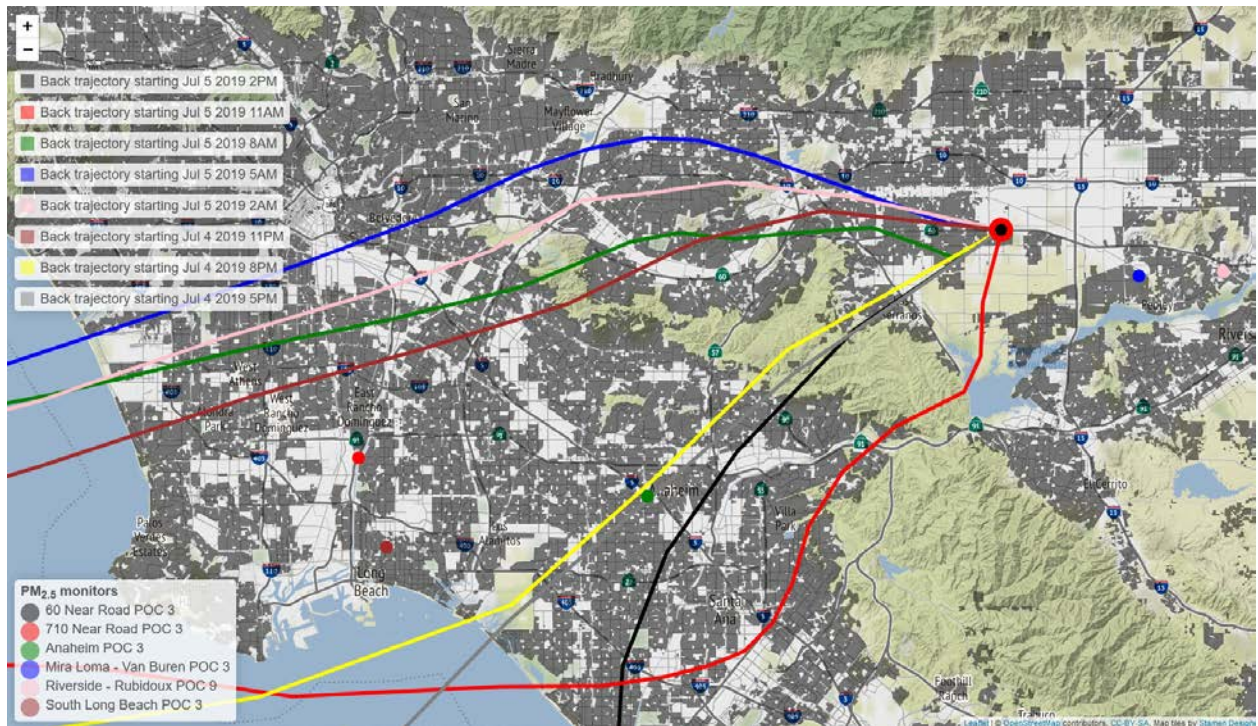

FIGURE II-7-33:
HYSPLIT BACK-TRAJECTORIES FROM 60 NEAR ROAD FOR JULY 4-5, 2019 OVERLAID ON A MAP OF THE SOUTH COAST AIR BASIN SHOWING RESIDENTIAL LAND USE (SHOWN IN GRAY).

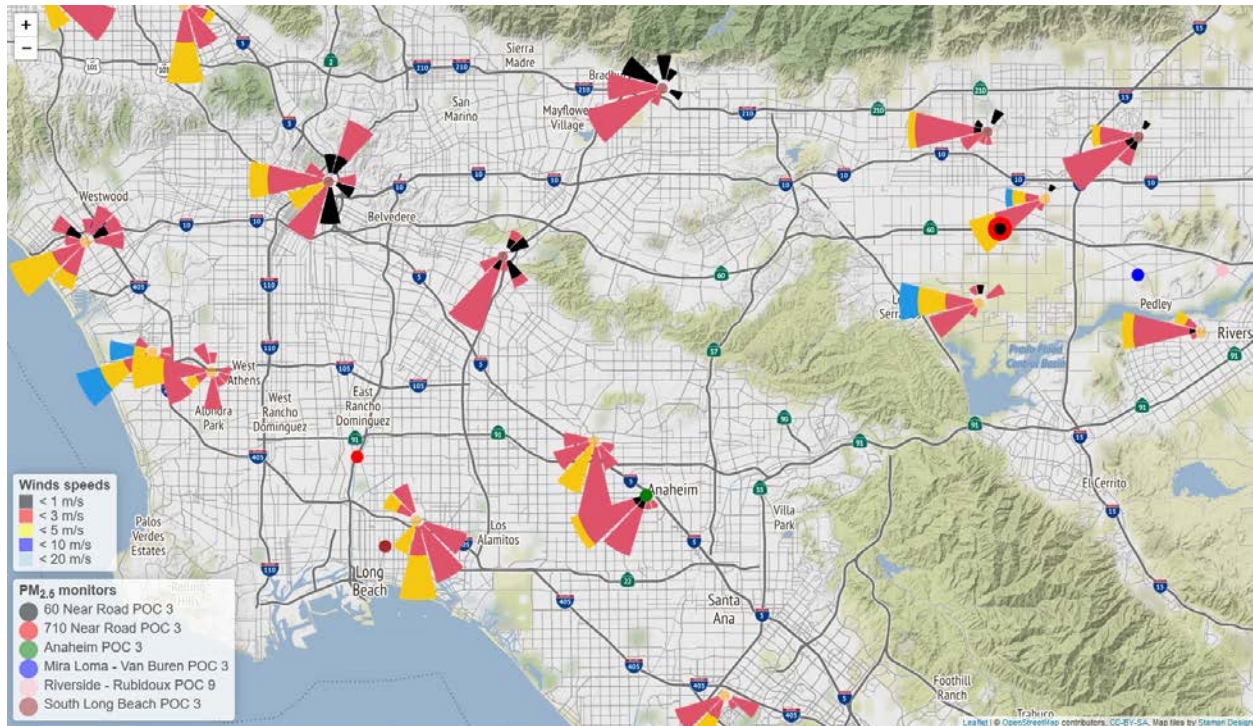

FIGURE II-7-34:
WIND ROSES FOR 9 PM ON JULY 4 THROUGH 2 PM ON JULY 5, 2019 THROUGHOUT THE SOUTH COAST AIR BASIN.

Figure II-7-35 shows time series plots of hourly PM_{2.5} data at selected stations with continuous PM_{2.5} instruments within the South Coast Air Basin for July 4-5, 2019. The concentrations peak at stations closer to the coast earlier than in inland areas (see Figure II-7-33 for monitor locations). This is consistent with the combination of 1) extensive fireworks use across the Basin, especially the most populated areas closer to the coast and 2) the dominant onshore flow that transports these emissions inland. The inland areas have local emissions as well as transported emissions from upwind areas.

FIGURE II-7-35:
HOURLY TIME SERIES FOR JULY 4-5, 2019 FOR PM_{2.5} MONITORING STATIONS IN THE SOUTH COAST AIR BASIN.

Figure II-7-36 through Figure II-7-39 show time series plots of PM_{2.5} (left axes) and windspeed (right axes) for the stations shown in Figure II-7-35 that have co-located wind data. The PM_{2.5} concentrations tend to be the highest during the periods with lowest windspeeds. This is consistent with elevated nearby emissions, such as fireworks and reflects the emission patterns of fireworks, which are typically used at nightfall.

FIGURE II-7-36:
HOURLY PM2.5 AND WINDSPEED FOR JULY 4-5, 2019 AT THE 60 NEAR ROAD STATION.

FIGURE II-7-37:

**FIGURE II-7-39:
HOURLY PM_{2.5} AND WINDSPEED FOR JULY 4-5, 2019 AT THE ANAHEIM STATION.**

Figure II-7-40 through Figure II-7-43 show scatter plots of PM_{2.5} versus hourly windspeed. This is the same data as shown in Figure II-7-36 through Figure II-7-39, except that the data are limited to 9 PM on July 4 through 5 PM on July 5, 2019 when we expect the greatest impacts from fireworks emissions. The NAAQS value (35 µg/m³) is shown as a horizontal line. Most PM_{2.5} measurements were below the NAAQS value whenever the winds were above approximately 5 knots, with the highest concentrations occurring at lower wind speeds. This pattern is consistent with elevated nearby emissions from fireworks accumulating to high concentrations during periods of lower ventilation and then diluting during periods of increased ventilation at higher windspeeds.

AT THE ANAHEIM STATION.**

Conclusion

South Coast AQMD posits that the 24-hour PM2.5 exceedances listed in Table II-7-1 in this report qualify for exclusion for analyses estimating base and future year design values for the PM2.5 attainment demonstration because the ambient data are not representative to characterize base period concentrations (see Table 1 of U.S. EPA, 2019). The annual fireworks emissions during Independence Day celebrations throughout the South Coast Air Basin impacting PM2.5 concentrations on July 4-5 are atypical, extreme, and unrepresentative events compared to typical summer days.

Attachment A: Evaluation of South Coast AQMD Rules

Attachment B: Most Stringent Measures Analysis of CARB’s Control Programs

Attachment C: Quantitative Analysis for Wood Burning Curtailment Threshold

Introduction

The South Coast Air Basin (Basin) was reclassified from “moderate” to “serious” nonattainment for the 2012 annual PM2.5 National Ambient Air Quality Standard (NAAQS or standard) of 12 µg/m³ effective December 9, 2020, with an attainment date of December 31, 2025.¹ Subpart 4 of the federal Clean Air Act (CAA) Part D specifies additional provisions for PM2.5 nonattainment areas. In particular, CAA Section 189(b) requires states to submit an attainment plan that meets “serious” area plan requirements and address attainment strategies for the 2012 annual PM2.5 standard.

Under CAA Section 189(b)(1)(B), a “serious” nonattainment area must demonstrate provisions to ensure that Best Available Control Measures (BACM), which includes Best Available Control Technology (BACT), for the control of PM from stationary sources are implemented no later than four years after the designation (or reclassification). In the Addendum to the General Preamble for the Implementation of Title I of the Clean Air Act Amendments of 1990 issued by U.S. EPA in 1994 (1994 Addendum),² BACM is defined as:

“The maximum degree of emissions reduction achievable from a source or source category which is determined on a case-by-case basis, considering energy, economic and environmental impacts and other costs.”

Similarly, BACT is defined as:

“An emission limitation which is based on the maximum degree of control that can be achieved. It is a case-by-case decision that considers energy, environmental and economic impact.”

The implementation of BACT is required for major stationary sources (i.e., sources that emit PM2.5 or any PM2.5 precursor in an amount exceeding 70 tons per year). BACT can be add-on control equipment or modification of the production processes or methods, including fuel cleaning or treatment and innovative fuel combustion techniques. In addition, BACT may be a design, equipment, work practice, or operational standard if imposition of an emissions standard is infeasible.

In addition to BACM and BACT, PM2.5 attainment plans must also include additional feasible measures that either assist with attainment or advance the attainment date by one year. Additional feasible measures may be implemented later than BACM/BACT but before the statutory “serious” area attainment date.

The control measure assessment for this plan seeks to evaluate the technological and economic feasibility of potential BACM and to identify additional feasible measures. The demonstration generally involves an analysis of South Coast AQMD’s control requirements as they compare to those in other jurisdictions. Other sources such as U.S. EPA guidance documents are also consulted. When South Coast AQMD’s

¹ 85 FR 71264

² 59 FR 41998, 42010

control requirements meet the BACM/BACT definition, no further analysis is required. When a regulation or control measure from another air basin or from U.S. EPA guidance is identified as more stringent than South Coast AQMD's regulation, the measure is analyzed for technological and economic feasibility. While South Coast AQMD is not required to adopt a measure just because it was adopted in another region, the rationale for rejecting such measures must be presented.

In addition to implementing BACM/BACT and additional feasible measures, "serious" nonattainment areas that request an extension under CAA Section 188(e) are required to demonstrate that the attainment plan includes the Most Stringent Measures (MSM). U.S. EPA defines MSM as:

"The maximum degree of emission reduction that has been required or achieved from a source or source category in any other attainment plans or in practice in any other states and that can feasibly be implemented in the area seeking the extension."

U.S. EPA notes that, "in some cases it may be possible for the MSM requirement to result in no more controls and no more emissions reductions in an area than result from the implementation of BACM and BACT." This is because the approach to identify potential MSM largely follows that of a BACM/BACT analysis except that more stringent criteria must be applied to reject Potential Control Measures (PCMs) based on technological or economic infeasibility. Therefore, staff first conducted a BACM/BACT analysis to identify a list of PCMs which were then analyzed by applying MSM criteria as detailed in the Control Measure Assessment section.

The 2016 AQMP included a BACM demonstration, which served both the 2006 and 2012 PM_{2.5} NAAQS. U.S. EPA approved the BACM demonstration for all sources of direct PM_{2.5} and PM_{2.5} precursors for the purposes of the 2006 PM_{2.5} NAAQS in accordance with the requirements of CAA Section 189(b)(1)(B) and 40 CFR 51.1010.³ As this represents the latest approved BACM demonstration for a PM_{2.5} NAAQS for the Basin, it was used as a starting point for this BACM demonstration. This demonstration sought to build upon and update the 2016 AQMP BACM demonstration, reflecting recent improvements in control technologies and identifying potential areas for improvements in South Coast AQMD rules. The analysis began with an overview of key PM stationary source categories which were identified through an examination of the emissions inventory. The applicable South Coast AQMD rules and corresponding rules in other air districts were also evaluated. Next, a multi-step process involving an evaluation of a wide range of sources was conducted to identify a list of PCMs. Finally, the PCMs were assessed for their technological and economic feasibility in the Control Measure Assessment section.

Identifying Key PM Source Categories

U.S. EPA recommends that the BACM analysis begin with a current detailed emissions inventory of the various sources that emit direct PM_{2.5} and PM_{2.5} precursors. Chapter 3 and Appendix III present a comprehensive emissions inventory which satisfies U.S. EPA's requirements. For the purposes of

³ 84 FR 3305

demonstrating BACM, control measures targeting only PM2.5, NOx, and NH3 were considered. However, although NOx and NH3 emissions contribute to PM2.5, air quality modeling demonstrates that direct PM2.5 emissions have the greatest impact on ambient PM2.5 concentrations. Therefore, identifying the top stationary source categories of direct PM2.5 emissions was taken as the first step and presented in Figure III-1.

FIGURE III-1
TOP STATIONARY SOURCE CATEGORIES OF DIRECT PM2.5 EMISSIONS IN 2018 AND 2030

The top three stationary source categories are cooking, paved road dust, and residential fuel combustion. Emissions from the latter category are dominated by wood combustion while cooking emissions are dominated by restaurant charbroilers. Based on this analysis, staff selected the following three stationary source categories for an in-depth control measure analysis:

- Residential Wood Combustion
- Paved Road Dust
- Commercial Cooking

In addition, Farming Operations – Livestock Waste, was selected as a key PM stationary source category after staff became aware of U.S. EPA’s proposed disapproval of several plan elements in San Joaquin Valley Air Pollution Control District’s (SJVAPCD) 2018 PM2.5 Plan.⁴ A central issue in U.S. EPA’s proposed

⁴ 87 FR 60494

disapproval relates to SJVAPCD's BACM analysis for NH₃ control measures at Confined Animal Facilities. Livestock waste is the primary NH₃ emission source at these facilities. Staff determined that an in-depth evaluation of existing rule requirements was warranted for this source category.

Existing Rules and Potential Control Measures for Key PM Source Categories

Existing rule requirements for the four key stationary sources identified in the previous section are summarized below. PCMs were identified by comparing existing control measures to the requirements in federal and state regulations and guidance, as well as the analogous rules in other air districts and agencies.

Residential Wood Combustion

Existing rule

South Coast AQMD Rule 445 Wood-Burning Devices (Amended October 27, 2020)

Rule 445 was first adopted in 2008 to reduce the emissions of particulate matter from wood-burning devices. The rule establishes requirements for the sale, operation, and installation of these devices. Specifically, Rule 445:

- Prohibits the installation of wood burning devices in new developments;
- Requires that wood-burning devices sold or installed for existing residential and commercial developments (additions, remodels, etc.) to be U.S. EPA certified or equivalent;
- Prohibits the burning of any product not intended for use as a fuel (e.g., trash) in a wood-burning device and requires commercial firewood sellers to only sell seasoned firewood (20 percent or less moisture content) from July through February; and
- Imposes a mandatory winter burning curtailment program that extends from November 1 through the end of February.

In addition to these regulatory requirements, South Coast AQMD has also implemented the Healthy Hearths™ program that includes a comprehensive education and outreach effort as well as financial incentives to encourage the public to switch to cleaner, gaseous-fueled hearth products.⁵ This program has incentivized the conversion of more than 10,000 wood-burning fireplaces to gas or electric fireplaces and continues to provide up to \$1,600 per unit for low-income households.

⁵ <http://www.aqmd.gov/home/programs/community/community-detail?title=wood-device-incentive-program>

South Coast AQMD continues to implement a wood-burning curtailment program through Rule 445. As a consequence of *Bahr v. EPA*, 836 F.3d 1218 (9th Cir. 2016), Rule 445 was amended in June 2020 to establish PM_{2.5} contingency provisions that would be automatically triggered in the event that the U.S. EPA determines that the Basin failed to meet any RFP requirement, meet any quantitative milestone, submit a quantitative milestone report, or attain a PM_{2.5} NAAQS by the attainment date. The amendment also expanded the curtailment program to the entire Basin instead of using a source-receptor specific approach. U.S. EPA's finding of failure to attain the 2006 24-hour PM_{2.5} standard by 2019 triggered the contingency provision and lowered the curtailment threshold from 30 to 29 µg/m³.⁶ In October 2020, the rule was amended to add ozone contingency provisions that would be triggered in the event that the U.S. EPA determines that the Basin failed to meet an RFP milestone or attain an ozone NAAQS by the applicable deadline. The contingency provision for applicable ozone NAAQS ~~will~~ will expand the curtailment season from the existing November through February to September through April. U.S. EPA approved the latest amendment of Rule 445 on March 8, 2022, excluding paragraph (g), "Ozone Contingency Measures," and paragraph (k), "Penalties," as satisfying PM_{2.5} contingency requirements.⁷

Federal and State rules and regulations

On March 16, 2015, U.S. EPA finalized the amendments for New Source Performance Standards (NSPS) for New Residential Wood Heaters (40 CFR Part 60 Subpart AAA).⁸ The 2015 NSPS significantly lowered the certification emission limits for wood-burning heaters to 4.5 g/hr in Phase I (on or after May 15, 2015) and 2.0 g/hr in Phase II (on or after May 15, 2020). In April 2020, U.S. EPA amended the 2015 NSPS for New Residential Wood Heaters to include minimum requirements for pellet fuels, sell-through provisions, and a clarification of prohibited fuels.⁹ The PM emission limits remained unchanged. Rule 445 references the NSPS for emission standards in the definition of U.S. EPA certified wood-burning heaters and is therefore as stringent as the newly promulgated NSPS.

Colorado, Idaho, Michigan, Oregon, Washington, Wisconsin, and Vermont require or provide incentives for cleaner wood-burning devices.¹⁰ Oregon requires that uncertified solid fuel burning devices located at a residential property be removed, destroyed and reported to the state when the home is sold.¹¹ However, heating devices (e.g., fireplaces, masonry heaters, central furnaces, etc.) are exempt.

Analogous rules in other air districts

SJVAPCD Rule 4901 Wood Burning Fireplaces and Wood Burning Heaters (Amended June 20, 2019)

San Joaquin Valley Air Pollution Control District (SJVAPCD) Rule 4901 includes a tiered mandatory curtailment program that establishes different curtailment thresholds for each county based on the type

⁶ 85 FR 57733

⁷ 87 FR 12866

⁸ 80 FR 13672

⁹ 85 FR 18448

¹⁰ <https://www.epa.gov/burnwise/ordinances-and-regulations-wood-burning-appliances>

¹¹ <https://www.oregon.gov/deq/FilterDocs/10aq011heatsmart.pdf>

of devices. During a level one episodic wood-burning curtailment, operation of wood-burning fireplaces and unregistered wood-burning heaters is prohibited, but properly operated, registered wood-burning devices are allowed to be used. During a level two episodic woodburning curtailment, operation of any wood-burning device is prohibited. In the “hot spot” counties of Madera, Fresno, and Kern, the level one PM_{2.5} threshold is 12 µg/m³, and the level two PM_{2.5} threshold is 35 µg/m³. In the remaining counties in the San Joaquin Valley (San Joaquin, Stanislaus, Merced, Kings, and Tulare), the level one PM_{2.5} threshold is 20 µg/m³, and the level two PM_{2.5} threshold is 65 µg/m³. Areas within the San Joaquin Valley that do not have natural gas service are not subject wood burning curtailment.

Rule 4901 prohibits the sale or transfer of any real property which contains wood-burning heaters (i.e., wood stove, pellet-fueled wood burning heater, or wood burning fireplace insert) that are not U.S. EPA Phase II certified. Rule 4901 also prohibits remodeling of a fireplace or chimney where the total cost exceeds \$15,000 and a local building permit is required, unless a gas-fueled, electric, or U.S. EPA certified device is installed that meets requirements in Title 40 CFR Part 60 Subpart AAA. Finally, wood-burning fireplaces are not allowed to be newly installed in areas with natural gas service at or below 3,000 feet elevation.

SMAQMD Rule 417 Wood Burning Appliances (Adopted October 26, 2006)

Staff evaluated the requirements of Sacramento Metro Air Quality Management District (SMAQMD) Rule 417 and found no requirements that were more stringent than those already incorporated in Rule 445.

BAAQMD Regulation 6 Rule 3 Wood-Burning Devices (Amended November 20, 2019)

Under Bay Area Air Quality Management District (BAAQMD) Regulation 6-3, the BAAQMD can issue a Winter Spare the Air Alert and require a Mandatory Burn Ban when air quality is forecast to be unhealthy due to elevated levels of fine particulate matter with some exemptions that allow wood-burning. The rule provides for limited exemptions in the following areas: (i) sole source of heat, (ii) non-functional, permanently installed heater, and (iii) loss of natural gas and/or electric power. In 2019, BAAQMD revised its wood-burning rule to provide for curtailments year-round with a curtailment threshold of 35 µg/m³. Regulation 6-3 prohibits remodeling of a fireplace or chimney where the total cost exceeds \$15,000 and a local building permit is required, unless a gas-fueled, electric, or U.S. EPA certified device is installed that meets requirements in Title 40 CFR Part 60 Subpart AAA. Regulation 6-3 requires exempt households whose sole source of heat is a wood-burning device to have U.S. EPA certified devices.

Utah Wood Burning Curtailment Program – Department of Environmental Quality’s Division of Air Quality Utah Administrative Code R307-302 Solid Fuel Burning Devices

The Utah wood burning curtailment program is geographically based with curtailment limited to the nonattainment counties of Box Elder, Cache, Davis, Salt Lake, Tooele, Utah, and Weber. The curtailment threshold is set at 25 µg/m³ PM_{2.5} 24-hour concentration. Similar to SJVAPCD Rule 4901, only counties specified in the public notification of curtailment are required to curtail wood burning.

Puget Sound Clean Air Agency Article 13: Solid Fuel Burning Device Standards (Adopted 11/10/88, amended 10/25/12) or Chapter 173-433 Washington Administrative Code

For the Tacoma-Pierce (TP) region, curtailment is limited based on device certification and location. TP certified stoves are those certified by U.S. EPA or Oregon state which can be up to 25 years old. Curtailment is classified as Stage 1 or Stage 2 air quality burn bans. Under Stage 1, where a PM_{2.5} ambient concentration of 35 µg/m³ within a 48-hour time is forecast, uncertified wood-burning device use is prohibited for King and Kitsap counties. Additionally, a Stage 1 curtailment applies to Pierce and Snohomish counties if a PM_{2.5} ambient concentration of 30 µg/m³ within a 72-hour time is forecast. As of October 2015, the sale or use of uncertified wood stoves is prohibited, so Stage 1 burn bans would mostly apply to fireplaces. A Stage 2 air quality burn ban, which includes all device types, may be declared if air quality is worsening rapidly. Air quality bans are also geographically based in that they may be called on a county and sub-county level. Pierce county now has three different air quality burn ban zones, that can be declared independently for burn day bans.

City of Portola, Plumas County, Wood Burning Rule – Chapter 15.10 of the City of Portola Municipal Code (Amended 10/13/21)

The City of Portola has a wood stove and fireplace ordinance which mandates episodic wood-burning curtailment from November to February whenever the Northern Sierra AQMD determines that the 24-hour average PM_{2.5} concentrations may exceed 30 µg/m³ and when adverse meteorological conditions are expected to persist. The ordinance contains a contingency provision which was recently triggered due to the Plumas County nonattainment area failing to attain the 2012 annual PM_{2.5} standard.¹² The contingency provision expanded the curtailment season to September through April and lowered the curtailment threshold to 20 µg/m³ when adverse meteorological conditions are expected to persist. The contingency provision will remain in effect until a new attainment plan addressing the 2012 annual PM_{2.5} standard is submitted to U.S. EPA.

Evaluation

Staff identified multiple provisions in other districts' rules which are potentially more stringent than those in South Coast AQMD Rule 445. Analyses of each of those provisions are presented below.

1. The curtailment threshold of 29 µg/m³ is higher than that in other districts' rules.

The level one curtailment thresholds in SJVAPCD Rule 4901 are lower than the curtailment threshold in South Coast AQMD Rule 445. However, in contrast to the county-specific approach in Rule 4901, the prohibition on wood-burning in Rule 445 is Basin-wide and applies to all solid fuel devices, regardless of certification. Rule 4901 permits the operation of U.S. EPA certified and registered wood-burning heaters during a level one curtailment period. Similarly, the City of Portola municipal code chapter 15.10 permits the operation of U.S. EPA certified wood-burning devices during curtailment.

¹² 87 FR 80076

The differences in regulatory approaches make a direct comparison between Rule 445 and other agencies' rules difficult as a quantitative matter. However, some general inferences can be made to assess the stringency of different rules qualitatively. For example, direct comparison between Rule 445 and SJVAPCD Rule 4901 requires looking at SJVAPCD's full curtailment ($65 \mu\text{g}/\text{m}^3$ threshold) to account for both all device types and all geographic locations, as Rule 445 does (at a $29 \mu\text{g}/\text{m}^3$ threshold). In the Basin, for the years 2016 through 2019, the PM_{2.5} 24-hour ambient concentration exceeded $65 \mu\text{g}/\text{m}^3$ two days during the wood-burning season, and exceeded the $35 \mu\text{g}/\text{m}^3$ standard on 56 days, including 7 days when PM_{2.5} concentrations were affected by wildfire smoke. With 480 days during the Basin's wood-burning season between 2016 and 2019, this represents only 0.4 percent and 12 percent of the days, respectively, that a No-Burn Day would have been declared if SJVAPCD Rule 4901 Level Two Episodic Curtailment requirements were in effect in the Basin. In contrast, South Coast AQMD declared no-burn days, which applied to the entire Basin, on 22 percent of days during the same period. Since Rule 445 does not differentiate between registered or unregistered devices or individual counties, if a SJVAPCD Level Two Episodic Curtailment were in effect in the Basin, it would have resulted in fewer curtailment days and consequently an increase in ambient PM_{2.5} emissions. The curtailment exemption for areas without natural gas service is another issue to consider. While Rule 445 contains a similar exemption, the South Coast Air Basin is a heavily urbanized area with widespread availability of natural gas service. On the contrary, the San Joaquin Valley has larger rural and undeveloped areas, and a significant portion of those areas do not have natural gas service. For example, most residences in Madera County do not have natural gas service.¹³ Therefore, although the exemption itself is similar, San Joaquin Valley likely has a higher proportion of the population that qualifies for this exemption and therefore greater amounts of wood burning occur in the San Joaquin Valley on curtailment days.

Staff also evaluated wood burning curtailment programs implemented in other jurisdictions. Although Utah's curtailment is nominally lower ($25 \mu\text{g}/\text{m}^3$) than the Basin's, only counties specified in the public notification of curtailment are required to curtail wood burning. In this regard, Utah's program is similar to that in SJVAPCD and is less stringent than the Basin-wide approach in Rule 445. BAAQMD has a similar curtailment approach as South Coast AQMD (not limiting either device type or location), but BAAQMD has a higher curtailment threshold ($35 \mu\text{g}/\text{m}^3$). The City of Portola municipal code chapter 15.10 is less stringent in several ways compared to Rule 445. First, certified devices are exempt from curtailment. Additionally, curtailment requires not only that forecasted PM_{2.5} exceed a numeric value but also that adverse meteorological conditions will persist as determined by the National Weather Service. Rule 445 does not have a provision requiring the persistence of adverse meteorological conditions. Additionally, the contingency measure in Portola's code, which temporarily lowered the threshold to $20 \mu\text{g}/\text{m}^3$, will sunset once a new attainment plan is submitted to the U.S. EPA and the threshold will revert to $30 \mu\text{g}/\text{m}^3$. Rule 445 does not contain a sunset provision for contingency measures.

A quantitative analysis, presented in Attachment C, was conducted to provide a robust comparison of the curtailment programs in Rule 445 and SJVAPCD Rule 4901. The analysis demonstrated that the current $29 \mu\text{g}/\text{m}^3$ is as stringent as the SJVAPCD Rule 4901 using Source Receptor Area (SRA) as a geographical unit

¹³ <https://ww2.valleyair.org/media/jkhaefnp/06-pm25-contingency-measure-sip-revision.pdf>

to define hotspot in a similar way that SJVAPCD R4901 defined. The South Coast Air Basin has 35 SRAs, of which population is larger than a county in SJVAPCD's jurisdiction. In addition, our daily forecast is provided for individual SRA's while SJVAPCD provide one forecast value to an entire county except two counties that are divided to two subareas each. Therefore, SRA is the equivalent unit to the SJVAPCD's county. However, per the suggestion from U.S. EPA Region 9, South Coast AQMD will consider lowering the Basin-wide curtailment threshold in Rule 445 to 25 $\mu\text{g}/\text{m}^3$. Therefore, control measure BCM-18 proposes to lower the residential wood burning curtailment threshold to 25 $\mu\text{g}/\text{m}^3$ while, as a whole, South Coast Rule 445 is at least as stringent as wood-burning curtailment rules adopted in other areas since no wood-burning device (registered or unregistered, or in any geographic location) may be operated on any day during the wood-burning season if the ambient PM_{2.5} 24-hour concentration is forecast to equal or exceed 29 $\mu\text{g}/\text{m}^3$. ~~In addition, a quantitative analysis, presented in Attachment C, was conducted to provide a robust comparison of the curtailment programs in Rule 445 and SJVAPCD Rule 4901.~~

2. The wood-burning curtailment season in Rule 445 (November-February) is narrower than that in BAAQMD Regulation 6, Rule 3 (year-round).

The majority of wood-burning activities in the Basin occur during November-February with reduced activity during the shoulder months of September, October, March and April. Rule 445 has a contingency provision to expand the curtailment season to the shoulder months. The contingency provision to extend the curtailment season will be triggered upon the issuance of a final determination by U.S. EPA that the South Coast Air Basin has failed to:

(A) meet a Reasonable Further Progress (RFP) requirement in an approved attainment plan for an applicable ozone NAAQS; or

(B) attain an applicable ozone NAAQS by the applicable attainment date.

The Basin, due to its climate, has virtually no residential wood-burning during the summer and, as such, expanding the curtailment program year-round would have no air quality benefit. This is supported by temporal allocation factors used in air quality modeling which reveal that there are no residential wood burning emissions for May-September. Conversely, the climate within the BAAQMD jurisdiction is appreciably cooler during the summer and wood-burning is more prevalent year-round (see Figure III-2).¹⁴ Given that difference, a year-round wood-burning curtailment program would be expected to yield additional emission reductions in the BAAQMD, but not in the Basin.

¹⁴ National Weather Service. <https://www.weather.gov/wrh/Climate?wfo=mtr>

FIGURE III-2
MONTHLY MEAN TEMPERATURE IN LOS ANGELES, RIVERSIDE, AND SAN FRANCISCO
BASED ON 2000-2023 DATA

Overall, Rule 445 is as stringent as BAAQMD's Regulation 6, Rule 3 since virtually no reductions will be achieved from a year-round curtailment due to the lack of wood-burning activities during summer months.

3. Other districts do not have a low-income exemption for households with an alternative source of heat.

Removal of the low-income exemption was identified as a control method to reduce PM emissions and it is evaluated further in the Appendix IV-A BCM-18.

4. Rule 445 contains an exemption from curtailment requirements for devices above 3,000 feet.

Due to atmospheric dynamics and transport, emissions from mountain communities above 3,000 feet likely have minimal to no impact on air quality in populated communities in the Basin. This is especially true on cold winter nights since a shallow boundary layer that is only a few hundred feet deep or less is present. Any emissions from the mountain communities above 3,000 feet will enter the residual layer and will not entrain down to the surface layer due to thermal stratification. On the next day when the mixing layer is developed and entrained to the residual layer, prevailing surface wind shifts to onshore flow (from the sea toward mountain summit), which will disperse the wood smoke laden air further away from the Basin.

Additionally, rural mountain communities in the Basin above 3,000 feet experience significant challenges in heating their homes during winter, especially those that may not have access to reliable natural gas or electricity service. Therefore, removing this exemption would jeopardize public safety as homes can become snowed in and residents must have a reliable means to heat their homes.

One option staff considered involved requiring U.S. EPA certified devices to qualify for the elevation-based exemption from curtailment. However, there are concerns as to whether households in rural mountain communities have the financial resources to procure and install such devices as many of these households are likely low-income. The cost concern is further elaborated under item 5. Staff does not consider it economically feasible to mandate U.S. EPA certified devices to qualify for the exemption.

5. Rule 445 does not have a provision requiring U.S. EPA certified devices to qualify for the sole source of heat exemption.

Data suggests that a very limited number of households in the Basin use wood as a fuel. In Los Angeles County, approximately 5,914 households burn wood as a primary source of heat out of an approximate total of 3,375,587 households (0.18 percent) according to U.S. Census data.¹⁵ The limited applicability of the sole-source of heat exemption suggests that the small emission reductions from requiring these households to have U.S. EPA certified devices would have an inconsequential impact on air quality. Additionally, many households subject to the sole source exemption are low-income and therefore do not have the financial resources to purchase a U.S. EPA certified wood stove. Costs for these units vary but can easily exceed \$4,000 without considering installation costs. If the wood stove is replacing an existing unit, then installation costs depend on the condition and compatibility of the exhaust pipe. If a new pipe is required, installation costs can exceed \$2,000. The high cost burden for low-income households combined with the minimal emission reductions that would be achieved suggest that this measure is not economically feasible.

6. Rule 445 does not have a provision requiring replacement of uncertified devices upon transfer or sale of a property.

To enforce this provision, SJVAPCD Rule 4901 requires sellers of residential property to submit documentation regarding the wood-burning devices located on the property even if there are none. However, the requirement to replace uncertified devices only applies to wood-burning stoves and inserts, and does not extend to fireplaces. According to the emissions inventory, 97 percent of wood-burning devices in the Basin are fireplaces. Furthermore, wood stoves and inserts tend to be more prevalent in colder and higher altitude regions. As stated in the previous section, the emissions from wood burning in these areas are not anticipated to significantly impact PM2.5 air quality in the Basin, particularly in areas already characterized by high PM2.5 levels. As such, applying the resale requirement in Rule 4901 to the Basin would not result in appreciable additional emission reductions and, for most home sales, enacting the resale provision in Rule 445 would lead to no emission reductions.

Staff is further concerned with the level of effort required for the small number of uncertified stoves and inserts in homes being sold. Given the much greater housing stock in the Basin relative to the SJVAPCD, South Coast AQMD would not have the resources to implement such a program. In addition, staff has

¹⁵ [United States Census Bureau - B25040: HOUSE HEATING FUEL - Census Bureau Table](#)

faced strong resistance from trade and building association groups as well as realtor associations due to the high cost of mandating and enforcing such a program.

In lieu of implementing this provision, South Coast AQMD has instead focused on incentives to convert wood-burning fireplaces to gaseous fueled and will consider to expanding the program to electric devices. South Coast AQMD has incentivized the conversion of more than 10,000 fireplaces to gaseous fueled, where practicable, and continues to do so by providing up to \$1,600 per unit in areas that typically see the highest concentrations of ambient PM_{2.5}. The voluntary incentive program is currently being successfully implemented and staff is exploring ways to expand eligibility criteria to further encourage voluntary participation. Since the resale provision in Rule 4901 does not require removal or upgrade of fireplaces, the incentive approach has been more effective at achieving emission reductions in the Basin.

7. Rule 445 does not have provisions addressing major remodels of fireplaces and chimneys.

SJVAPCD Rule 4901 requires installation of a U.S. EPA certified, gas-fueled, or electric device during a remodel of a fireplace or chimney that exceeds \$15,000 and requires a building permit. BAAQMD Regulation 6-3 has a similar provision. Under Rule 445, remodels are permitted if a health or safety issue exists and the wood-burning device is repaired within its existing footprint.^{16,17} ~~However While, Rule 445 does not have explicit provisions addressing major remodels of fireplaces or chimneys, it does restrict the sale, supply, and installation of wood burning devices unlike rules in other air districts.~~

The provisions in other districts' rules referencing remodels that exceed \$15,000 and require a building permit suggest a substantial change to the appearance and/or functional utility of the fireplace. An example of such a change would be a homeowner who intends to demolish an existing fireplace to install a larger fireplace. In this instance, Rule 445 section (d)(2) is as stringent as, if not more stringent than, SJVAPCD Rule 4901 section 5.3 and BAAQMD Regulation 6, Rule 3 section 307 by requiring replacement units to be a U.S. EPA certified insert, masonry or pellet fueled heater, or a gaseous-fueled fireplace. Masonry and pellet fueled stoves have very low emission factors similar to U.S. EPA certified units. Importantly, Rule 445 does not have an up to \$15,000 cost exemption or building permit requirement to trigger the requirements under (d)(2). Rule 445 always requires a less polluting alternative when replacing any wood burning device. Rule 445 is also more stringent because it prohibits the sale or installation of anything other than the listed types, which applies regardless of the size of project or whether it needs a building permit. Rule 445 is likely more enforceable as a sale/installation ban, imposed on companies, than provisions addressing individual residential building projects.

¹⁶ <http://www.aqmd.gov/docs/default-source/rule-book/support-documents/rule-445/detailed-rule-445-information.pdf?sfvrsn=13>

¹⁷ South Coast AQMD, Final Staff Report for Proposed Amended Rule 445 – Wood-Burning Devices. June 5, 2020

Farming Operations – Livestock Waste

Existing rules

Emissions from livestock waste in farming operations are regulated by Rules 223 and 1127.

South Coast AQMD Rule 223 Emission Reduction Permits for Large Confined Animal Facilities (Adopted June 2, 2006)

Rule 223 requirements apply to large Confined Animal Facilities (CAFs) above certain size thresholds. Dairies with at least 1,000 milking cows, poultry facilities with at least 650,000 birds, and horse facilities with at least 2,500 horses qualify as large CAFs. Pertaining to manure management, the dairy provisions require that owners/operators implement at least six of 12 corral measures, two of seven solid manure or separated solids handling measures, one of eight liquid manure handling measures, and two of four land application measures. A poultry large CAF owner/operator must implement at least one of seven solid manure or separated solids handling measures, and one of eight liquid manure handling measures.

South Coast AQMD Rule 1127 Emission Reductions from Livestock Waste (Adopted August 6, 2004)

Rule 1127 was adopted on August 6, 2004 to reduce emissions of ammonia, VOC, and PM₁₀ emissions from dairy livestock waste. Rule 1127 applies to dairy farms with 50 or more cows, heifers, and/or calves and to manure processing operations, such as composting operations and anaerobic digesters. Rule 1127 requires the implementation of Best Management Practices (BMPs) to minimize fugitive dust, ammonia, and VOC emissions. Manure disposal is permitted only if the destination is a manure processing facility designed to reduce ammonia and VOC emissions from unprocessed manure, agricultural land within the South Coast AQMD approved for the spreading of manure, or a combination of the above options.

Federal and State rules and regulations

There are no federal or State regulations describing BACM for this source category. However, in 2017, U.S. EPA and the United States Department of Agriculture (USDA) published a reference guide that provides a compilation of control measures that achieve emission reductions from livestock and poultry operations.¹⁸

Analogous rules in other air districts

SJVAPCD Rule 4570 Confined Animal Facilities (Amended October 21, 2010)

Rule 4570 limits emissions of VOC and NH₃ from Confined Animal Facilities. Rule 4570's regulatory thresholds include facilities with at least 500 milking cows, 3,500 beef cattle, 7,500 calves, heifers, or other cattle, 400,000 heads of chicken and ducks, 100,000 heads of turkey, 3,000 heads of swine and horses, and 15,000 heads of sheep, goats, or any combination of the two. Rule 4570 is more stringent regarding applicability than Rule 223 for milk cows (1,000 milk cows in South Coast AQMD vs. 500 milk cows in

¹⁸ https://www.epa.gov/sites/default/files/2017-01/documents/web_placeholder.pdf

SJVAPCD), and for chickens and ducks (650,000 birds in South Coast AQMD vs. 400,000 birds in SJVAPCD). Rule 4570 also made certain feed and housing menu items mandatory for dairies and poultry facilities. However, South Coast AQMD Rule 1127 has lower applicability thresholds for cows, heifers and/or calves. Rule 223 also has a lower applicability for horse facilities (2,500 in South Coast AQMD vs. 3,000 in SJVAPCD), however there are no CAFs with greater than 2,500 horses in San Joaquin Valley.¹⁹

For corral mitigation measures in dairy operations, Rule 4570 has nine mitigation measures, six of which are mandatory and one additional measure that is required from the remaining three. South Coast AQMD Rule 223 requires at least six control measures from 10 Class One mitigation measures and two Class Two mitigation measures. For one Class One mitigation measure – inspect water pipes and troughs and repair leaks – South Coast AQMD Rule 223 has a higher frequency requirement than SJV Rule 4570. In addition, South Coast AQMD Rule 1127, which applies to dairies with 50 or more cows, requires facilities to choose at least five of the seven corral mitigation measures. Rule 4570 contains two solid waste control measures, from which facilities are required to choose at least one. South Coast AQMD Rule 223 has four Class One mitigation measures and three Class Two mitigation measures, from which facilities are required to choose at least two. With regard to liquid waste mitigation measures in dairies, operators are required to choose at least one of the four mitigation measures listed in Rule 4570. South Coast AQMD Rule 223 has five Class One mitigation measures and three Class Two mitigation measures, from which facilities are required to choose at least one. South Coast AQMD Rule 1127 requires that manure removed must be either treated at an approved manure processing operation or applied on agricultural land with local approval.

BAAQMD Regulation 2 Rule 10 Large Confined Animal Facilities (Adopted July 19, 2006)

Rule 2-10 is a permit rule that limits emissions of VOCs, NOx and PM10 from large CAFs. The applicability threshold is the same as in South Coast AQMD Rule 223. Rule 2-10 requires Reasonably Available Control Technology (RACT) to be implemented for a large CAF.

SMAQMD Rule 496 Large Confined Animal Facilities (Adopted August 24, 2006)

Rule 496 applies to large CAFs with the same regulatory threshold as South Coast AQMD Rule 223. Regarding corral mitigation measures in dairies, Rule 496 has 15 Class One mitigation measures and three Class Two mitigation measures from which facilities are required to choose at least six. South Coast AQMD Rule 223 requires the same number of control measures (at least six) from ten Class One mitigation measures and two Class Two mitigation measures. For controlling emissions from solid waste, Rule 496 requires the dairy operators to choose at least two mitigation measures from five Class One mitigation measures and three Class Two mitigation measures; South Coast AQMD Rule 223 has four Class One mitigation measures and three Class Two mitigation measures, from which facilities are required to choose at least two. Regarding liquid waste mitigation measures, Rule 496 has five Class One mitigation measures and five Class Two mitigation measures, from which facilities are required to choose at least

¹⁹ San Joaquin Valley Air Pollution Control District 2018 Serious Area Plan for the 2012 Annual PM2.5 Standard, Appendix C. <https://www.valleyair.org/pmplans/documents/2018/pm-plan-adopted/C.pdf>

one. South Coast AQMD Rule 223 has similar requirements at which operators are required to choose at least one measure from five Class One mitigation measures and three Class Two mitigation measures.

ICAPCD Rule 217 Large Confined Animal Facilities Permits Required (Amended February 9, 2016)

Imperial County Air Pollution Control District (ICAPCD) Rule 217 was adopted on October 10, 2006 and limits ammonia and VOC emissions from large confined animal facilities.²⁰ Following adoption of the 2016 amendment, the requirements are now equally stringent to SJVAPCD Rule 4750, and thus the applicability thresholds are lower than those in South Coast AQMD Rule 223.²¹

Evaluation

SJVAPCD Rule 4750 and ICAPCD Rule 217 have lower applicability thresholds than South Coast AQMD Rule 223. Staff evaluated the feasibility and effectiveness of lowering the rule applicability thresholds for dairies and poultry facilities. Staff also evaluated the control measures provided in the U.S. EPA and USDA reference guide. The evaluation can be found in the Control Measure Assessment section.

Paved Road Dust

Existing rules

Emissions from paved road dust are regulated by multiple South Coast AQMD rules.

South Coast AQMD Rule 1186 PM₁₀ Emissions from Paved and Unpaved Roads and Livestock Operations (Amended July 11, 2008)

Rule 1186 controls emissions of particulate matter from paved and unpaved public roads, and livestock operations. It establishes requirements to prevent material from being deposited on roadways and also requires local jurisdictions to procure certified street sweeping equipment. Rule 1186 requires new or widened roads to be constructed with curbing or, as an alternative, paved shoulders. Local governments are also required to remove material deposited onto roads as a result of wind, water erosion, or by other means, and are also required to use only South Coast AQMD Rule 1186-certified street sweepers which have a minimum pick-up efficiency of 80 percent and limit entrained PM₁₀ emissions to no more than 200 mg/m. Rule 1186 also requires unpaved access connections and unpaved feed lane access areas in livestock operations to be treated. All grinding activities are limited to 2 to 5 p.m. if visible emissions are detected.

²⁰ <https://apcd.imperialcounty.org/wp-content/uploads/2020/01/1RULE217.pdf>

²¹ San Joaquin Valley Air Pollution Control District 2018 Serious Area Plan for the 2012 Annual PM_{2.5} Standard, Appendix C. <https://www.valleyair.org/pmplans/documents/2018/pm-plan-adopted/C.pdf>

South Coast AQMD Rule 1157 PM10 Emission Reductions from Aggregate and Related Operations (Amended September 8, 2006)

Rule 1157 requires access improvements which are intended to reduce the amount of material tracked out from a facility onto surrounding paved public roads.

South Coast AQMD Rule 403 Fugitive Dust (Amended June 3, 2005)

Rule 403 requires access improvements for sites greater than 5 acres and all material tracked out from applicable sources must be removed at the conclusion of the workday or at any time it extends more than 25 feet from a site.

South Coast AQMD Rule 403.2 Fugitive Dust from Large Roadway Projects (Adopted June 3, 2022)

Rule 403.2 reduces potential fugitive dust impacts to communities near large roadway projects and prohibits certain large roadway project activities that generate dust and are in close proximity to sensitive receptors and areas of public exposure. Rule 403.2 includes additional requirements related to dust control, notification to nearby receptors, project signage, and recordkeeping.

Federal and State rules and regulations

Staff evaluated the requirements of U.S. EPA's Fugitive Dust Background Document and Technical Information Document for BACM and found no requirements that were more stringent than those already incorporated in the South Coast AQMD rules for this source category.²²

There are no State regulations/policies describing BACM for this source category.

Analogous rules in other air districts

SJVAPCD Rule 8061 Paved and Unpaved Roads (Amended August 19, 2004)

SJVAPCD Rule 8061 establishes a minimum sweeping frequency of once per month for roads with paved curbs that have been determined to have the greatest potential for dirt and silt loadings. For unpaved roads, on any unpaved road segment with 26 or more Annual Average Daily Traffic (AADT), the owner/operator shall limit visible dust emission to 20 percent opacity and comply with the requirements of a stabilized unpaved road or shall implement an APCO-approved Fugitive PM10 Management Plan. Within an urban area, Rule 8061 requires that all new roads be paved. For existing paved roads in urban areas with unpaved shoulders, Rule 8061 requires paving or stabilizing a 4-foot shoulder on 50% of the roads with the highest AADT.

²² <https://nepis.epa.gov/Exe/ZyPDF.cgi/2000JCJE.PDF?Dockey=2000JCJE.PDF>

SMAQMD Rule 403 Fugitive Dust (Adopted August 3, 1977)

Staff evaluated the requirements of SMAQMD Rule 403 and found no requirements that were more stringent than those already incorporated in the South Coast AQMD rules for this source category.

BAAQMD has no rule for this source category.

Evaluation

Staff evaluated the feasibility and effectiveness of establishing minimum street sweeping frequencies and enhancing street cleaning for roads with higher silt loadings. The evaluation can be found in the Control Measure Assessment section.

Commercial Cooking

Existing rule

South Coast AQMD Rule 1138 Control of Emissions from Restaurant Operations (Adopted November 14, 1997)

South Coast AQMD regulates VOC and PM emissions from chain-driven charbroilers through Rule 1138. Rule 1138 covers chain-driven charbroilers cooking 875 pounds of meat or more per week, applicable to mostly large (fast food) chain operations. The rule requires the installation of flameless catalytic oxidizers, or equivalent control devices, to chain-driven charbroilers. Currently, under-fired charbroilers are not regulated by Rule 1138.

Federal and State rules and regulations

There are no federal or State regulations/policies describing BACM for this source category.

Analogous rules in other air districts and local agencies

SJVAPCD Rule 4692 Commercial Charbroiling (Amended June 21, 2018)

Rule 4692 reduces PM emissions by requiring catalytic oxidizers for chain-driven charbroilers cooking 400 pounds of meat or more per week. This threshold is more stringent than South Coast AQMD Rule 1138 which applies to chain-driven charbroilers cooking 875 pounds of meat or more per week. Rule 4692 requires that chain-driven charbroilers be equipped with a catalytic oxidizer that achieves minimum control efficiencies of 83 percent for PM10 and 86 percent for VOCs. Catalytic oxidizers certified by South Coast AQMD are also deemed compliant. In its 2018 amendment, SJVAPCD expanded Rule 4692 applicability to include under-fired charbroilers. Operators of under-fired charbroilers are required to submit a one-time report and register the equipment in lieu of obtaining a permit. There are no registration and reporting requirements for under-fired charbroilers in Rule 1138. However, there are limited filing requirements for owners or operators of commercial charbroilers under Rule 222.

BAAQMD Regulation 6, Rule 2 Commercial Cooking Equipment (Adopted December 5, 2007)

Regulation 6-2 requires controls on chain-driven charbroilers and under-fired charbroilers meeting the requirements of: exempting less than 400 lbs of meat per week for chain-driven charbroilers and exempting less than 800 lbs of meat per week for under-fired charbroilers; installation of a certified catalytic oxidizer emitting 1.3 lbs of PM₁₀ and 0.32 lbs of VOC per 1,000 lbs of beef cooked, or a control device emitting 0.74 lbs of PM₁₀ per 1,000 lbs of beef cooked for chain-driven charbroilers; PM₁₀ emissions limit no more than 1.0 lb per 1,000 lbs of beef cooked and installation of a certified control device for new and existing under-fired charbroilers. These emission limits are similar to the limits that would be achieved by a South Coast AQMD certified catalytic oxidizer.

BAAQMD does have a lower exemption limit for chain-driven charbroilers (400 lb or less of beef cooked per week) in comparison to South Coast AQMD (875 lb or more per week). However, South Coast AQMD Rule 1138 is applicable to all types of meat (e.g., fish, chicken, pork, etc.). While beef (e.g., hamburger and steak) does have the highest amount of PM and VOC emissions per pound, a large portion of the overall types of meat cooked include meats other than beef. In the Bay Area, 58 percent of meat charbroiled is not beef.²³ Furthermore, the BAAQMD exemption threshold of 800 lb or less of beef for under-fired charbroilers is very close to the 875 lb or less exemption for chain-driven charbroilers since, at this volume of throughput, charbroilers tend to be chain-driven and not under-fired and a permit may be required.

Finally, no under-fired charbroiler emissions control device meeting the requirements of BAAQMD Regulation 6 Rule 2 has been certified in the Bay Area ~~and there is no active enforcement of this provision.~~²⁴

New York City Department of Environmental Protection (NYC DEP), Title 24 of the Administrative Code, Section 24-149.4 Commercial Char Broilers (Amended May 6, 2016)

Passed in May 2016, this code requires the installation of a control device which is certified to provide at least 75 percent emission reductions for new under-fired charbroilers and for any new or existing chain-driven charbroiler used to cook 875 lbs or more of meat per week. Registration and the payment of a \$100 administration fee are required for existing charbroiler units. Consideration of control requirements for existing under-fired charbroilers was pushed back due to feasibility questions and higher cost of retrofitting existing operations. Based on conversations with NYC DEP, there has been no active enforcement of the under-fired charbroiler provisions in this code.²⁵

City of Aspen, Colorado, Administrative Code Section 13.08.100. Restaurant Grills

This code applies to commercial charbroilers installed after April 25, 1983. Charbroilers installed after April 25, 1983 but before January 1, 1993 are required to be equipped with an emission control device

²³ 2007 Bay Area Air Quality Management District Staff Report, Regulation 6, Rule 2: Commercial Cooking Equipment

²⁴ Telephone call with Eric Pop, Compliance and Enforcement staff at BAAQMD, 5/5/23

²⁵ Email correspondence with staff at NYC DEP, 9/14/23

that reduces uncontrolled PM10 emissions by at least 90 percent if the charbroiler is used to cook high-fat-content meat. All charbroilers newly installed on or after January 1, 1993 are subject to PM10 emissions control at 90 percent efficiency, unless a charbroiler is replaced with another charbroiler that is less than or equal to the cooking surface of the charbroiler being replaced.

Ventura County Air Pollution Control District Rule 74.25 Restaurant Cooking Operations

All chain-driven charbroilers cooking over 875 lbs meat/week require catalytic oxidizers. Staff did not identify any more stringent provisions than those in Rule 1138.

Evaluation

Staff assessed the potential emission reduction opportunities of lowering the regulatory threshold for chain-driven charbroilers. The evaluation can be found in the Control Measure Assessment section. As of September 2023, staff confirmed that jurisdictions with measures in place that require installing control devices for under-fired charbroilers (BAAQMD and NYC DEP) do not have any known installations that meet the applicable measure requirements. As these jurisdictions were not able to identify an example of an installed certified control device, it makes it difficult to demonstrate that available technologies could achieve emission reductions in practice. Therefore, staff does not propose a potential control measure for under-fired charbroilers. Nevertheless, South Coast AQMD will continue discussions and collaboration with other air districts and CARB to continually assess the state of control technology for under-fired charbroilers.

Identifying Potential Control Measures

While the previous section focused on an in-depth analysis of several key PM source categories, the BACM demonstration is required to identify potential opportunities to reduce emissions across all applicable source categories. To accomplish this, U.S. EPA recommends that nonattainment air districts first identify the emission reduction programs that have already been implemented at the federal, state or local air district level. Next, U.S. EPA recommends that air districts examine additional control measures adopted for other nonattainment areas to attain the ambient air quality standards as expeditiously as practicable. To demonstrate that South Coast AQMD has considered all available measures, a multi-step analysis that consulted various sources was conducted. The following sections summarize the analysis.

Step 1 – Other Districts’ Control Measures

This portion of the analysis focused on the identification of air districts’ rule requirements that are more stringent than those in South Coast AQMD rules. A detailed evaluation of South Coast AQMD rule requirements can be found in Attachment A. It shows that, in general, South Coast AQMD’s current rules and regulations are equivalent to or more stringent than those developed by other air districts. However, in some areas, existing source-specific rules may be amended to lower exemption thresholds and/or emissions standards, promote cleaner technologies, or add additional best management practices. The

key findings are summarized in Table III-1, while the Control Measure Assessment section contains an in-depth feasibility discussion for each measure.

TABLE III-1
AIR DISTRICTS' RULE REQUIREMENTS THAT ARE MORE STRINGENT THAN THOSE IN SOUTH COAST AQMD RULES

Rule #	Evaluation
223	SJVAPCD Rule 4570 has lower applicability thresholds than those in Rule 223 for milk cows (1,000 milk cows in South Coast AQMD vs. 500 milk cows in SJVAPCD), and for chickens and ducks (650,000 birds in South Coast AQMD vs. 400,000 birds in SJVAPCD). Staff evaluated the feasibility and effectiveness of extending rule applicability to dairies and certain poultry facilities using a lower size threshold, and the assessment can be found in the Control Measure Assessment section.
445	SJVAPCD Rule 4901 and BAAQMD Regulation 6, Rule 3 have more stringent requirements. For details, refer to the previous section. Staff analyzed the feasibility of incorporating the more stringent requirements and the assessment can be found in the Control Measure Assessment section.
1111	BAAQMD Regulation 9, Rule 4 establishes a zero NOx emission limit for new natural gas-fired space heaters with a capacity < 175,000 Btu/hr beginning in 2029, which is more stringent than the 14 ng/J NOx emission limit in Rule 1111. Staff evaluated the feasibility and effectiveness of lowering the emission limit and the assessment can be found in the Control Measure Assessment section.
1117	SJVAPCD Rule 4353 contains emission limits for PM10 which are not in Rule 1117. Staff evaluated the feasibility of incorporating these emission limits and the assessment can be found in the Control Measure Assessment section.
1121	BAAQMD Regulation 9, Rule 6 establishes a zero NOx emission limit for new natural gas-fired water heaters and boilers, which is more stringent than the NOx emission limits in Rule 1121. Implementation of the zero NOx limit follows a phased approach depending on the capacity, but all new heaters and boilers up to 2 MMBtu/hr are required to comply by 2031. Staff evaluated the feasibility and effectiveness of lowering the emission limit and the assessment can be found in the Control Measure Assessment section.
1138	SJVAPCD Rule 4692 has a lower applicability threshold (400 vs. 875 lbs of meat or more per week in South Coast AQMD) for chain-driven charbroilers. BAAQMD Regulation 6, Rule 2 applies to under-fired charbroilers with combined total grill surface area of at least 10 square feet, purchasing 1,000 lbs of beef or more per week, and cooking 800 lbs of beef per week. Staff evaluated the feasibility of lowering the regulatory threshold of chain-driven charbroilers from 875 to 400 lbs of meat or more per week and extending applicability to under-fired charbroilers. The assessment can be found in the Control Measure Assessment section.
1146	SJVAPCD Rule 4320 has more stringent NOx emission limits than Rule 1146 for boilers, steam generators, and process heaters greater than or equal to 5 MMBtu/hr. For natural gas-fired boilers between 5 and 20 MMBtu/hr, the NOx limit is 5 ppm in Rule 4320, while

Rule #	Evaluation
	the corresponding NOx limits are 7 to 9 ppm in Rule 1146. In addition, for natural gas-fired units that are greater than 20 MMBtu/hr, the NOx limit is 2.5 ppm in Rule 4320 compared to 5 ppm in Rule 1146. Unlike Rule 1146, which sets mandatory emission limits, Rule 4320 has an option for facilities to pay an annual emission mitigation fee in lieu of meeting the NOx limits. Staff evaluated the feasibility of lowering emission limits in Rule 1146 and the assessment can be found in the Control Measure Assessment section.
1186	SJVAPCD Rule 8061 requires municipalities to sweep paved roads at least once per month with PM10 efficient units. For unpaved roads, on any unpaved road segment with 26 or more AADT, the owner/operator shall limit visible dust emission to 20 percent opacity and comply with the requirements of a stabilized unpaved road, or shall implement an APCO-approved Fugitive PM10 Management Plan. Within an urban area, this rule requires all new roads to be paved. Staff evaluated the feasibility of these requirements and the assessment can be found in the Control Measure Assessment section.

The following sections present an in-depth analysis of SIPs from other 2012 annual PM2.5 NAAQS nonattainment areas (see Table III-2). South Coast AQMD staff evaluated the control measures in these SIPs and analyzed the corresponding adopted or amended rules, if applicable. Evaluation of the control strategies for these nonattainment areas is a critical component of this BACM demonstration and ensures that South Coast AQMD incorporates the most effective PM2.5 measures being applied across the nation.

TABLE III-2
2012 ANNUAL PM2.5 NAAQS NONATTAINMENT STATUS AND ATTAINMENT YEAR

NONATTAINMENT AREA	2012 Annual PM2.5 Standard	
	Classification	Attainment Year
Los Angeles-South Coast Air Basin, CA	Serious	2025
San Joaquin Valley, CA	Serious	2025
Plumas County, CA	Serious	2025
Imperial County, CA	Moderate	2021
Allegheny County, PA	Moderate	2021

PM2.5 Nonattainment Areas, as of 1/30/2023, are posted in
<https://www3.epa.gov/airquality/greenbook/kbtcw.html>.

San Joaquin Valley, CA

On November 15, 2018, San Joaquin Valley APCD adopted the 2018 PM_{2.5} Plan to address U.S. EPA's 1997 (annual, 15 µg/m³ and 24-hour, 65 µg/m³), 2006 (24-hour, 35 µg/m³), and 2012 (annual, 12 µg/m³) PM_{2.5} standards.²⁶ The plan committed to adopt the following eight regulatory control measures.

- SJVAPCD Rule 4311 Flares

Rule 4311 controls emissions from flares at oil and gas production facilities, sewage treatment plants, waste incineration and petroleum refining operations. Flare operators are required to submit flare minimization plans, perform extensive monitoring and record keeping, submit reports of planned and unplanned flaring activities, and meet petroleum refinery SO₂ performance targets. In its 2018 PM_{2.5} Plan, SJVAPCD committed to pursue 0.05 tpd of additional NO_x emissions reductions.

Rule 4311 was amended on December 17, 2020 and has NO_x and VOC emissions limits that are 0.018 to 0.06 lbs/MMBtu and 0.008 to 0.038 lbs/MMBtu, respectively. South Coast AQMD Rule 1118 (Control of Emissions from Refinery Flares; amended 7/7/17) requires flare minimization plans, reports of planned and unplanned flaring activities, and record keeping for petroleum refineries. South Coast AQMD Rule 1118.1 (Control of Emissions from Non-Refinery Flares; adopted in January 2019, limits NO_x emissions at 0.018 to 0.06 lbs/MMBtu and VOC emissions at 0.008 to 0.038 lbs/MMBtu from non-refinery flare gases, including digester gas, landfill gas, produced gas, and other flare gas. The NO_x limits in South Coast AQMD Rule 1118.1 are as stringent as those in SJVAPCD Rule 4311.

- SJVAPCD Rule 4306 Boilers, Steam Generators, and Process Heaters – Phase 3 and Rule 4320 Advanced Emission Reduction Options for Boilers, Steam Generators, and Process Heaters Greater than 5.0 MMBtu/hr.

A wide range of industries are subject to Rules 4306 and 4320, including electrical utilities, cogeneration, oil and gas production, petroleum refining, manufacturing and industrial processes, food and agricultural processing, and service and commercial facilities. The 2018 PM_{2.5} Plan considered potential measures including lowering emission limits and further lowering the more stringent advanced emission reduction option limit.

Both Rule 4306 and Rule 4320 were amended on December 17, 2020 to include the latest generation of ultra-low NO_x burners, SCR, and low NO_x burners combined with SCR. Rule 4306 has tiered NO_x emissions requirements. Tier 1 limits are required until December 30, 2023 and Tier 2 limits are enforced beginning December 31, 2023. For Tier 1 units operated on natural gas with a rated heat input equal to or less than 20 MMBtu/hr, a NO_x limit of 9 ppm for thermal fluid

²⁶ <https://www.valleyair.org/pmplans/documents/2018/pm-plan-adopted/2018-Plan-for-the-1997-2006-and-2012-PM2.5-Standards.pdf>

heaters with a total rated heat input between 5 and 20 MMBtu/hr to be implemented by 2023–2029. Rule 4320 requires fire-tube boilers and all other equipment greater than 20 MMBtu/hr to meet 2.5 ppm NO_x limit by 2023.

South Coast AQMD Rule 1146 (Emissions of Oxides of Nitrogen from Industrial, Institutional, and Commercial Boilers, Steam Generators, and Process Heaters; amended 12/4/20) currently limits NO_x emissions from thermal fluid heaters to 12 ppm. While 9 ppm is feasible for new burners upon replacement, the 12 ppm NO_x emission limit was established at the time of rule development. Lowering the emission limit from 12 ppm to 9 ppm for retrofits involves higher costs ranging from \$58,000 to \$523,000 per ton of NO_x reduced.²⁷ SJVAPCD Rule 4320 provides the flexibility to comply with the lower NO_x emission limit through paying an annual mitigation fee as an option in lieu of meeting the limit, whereas the emission limits in Rule 1146 are mandatory.

- SJVAPCD Rule 4354 Glass Melting Furnaces

Rule 4354 limits emissions of NO_x, CO, VOC, SO_x, and PM₁₀ from glass manufacturing plants that make flat glass (window and automotive windshields), container glass (bottles and jars), and fiberglass (insulation). SJVAPCD committed to pursue the potential reductions of NO_x emissions for container glass furnaces using ultra-low NO_x control technologies such as catalytic filtration, oxy-fuel combined with SCR, and other methods.

Rule 4354 was amended on December 16, 2021 and requires container glass melting furnaces to meet a 1.5 lbs of NO_x limit per ton of glass produced until December 31, 2023. On and after January 1, 2024, the phase I NO_x limit is 1.1 lbs per ton of glass produced and the phase II NO_x limit is 0.75 lbs per ton of glass produced. For the same type of glass melting furnaces, the SO_x emission limit is 1.1 lbs per ton of glass produced until December 31, 2023 and 0.85 lbs per ton of glass produced on and after January 1, 2024.

South Coast AQMD Rule 1117 (Emissions from Container Glass Melting and Sodium Silicate Furnaces; amended 6/5/20) has comparable emission limits of NO_x and SO_x for container glass melting furnaces. Through 2023, NO_x (0.75 lbs per ton of glass produced) and SO_x (1.1 lbs per ton of glass produced) emission limits in Rule 1117 are at least as stringent as or even more stringent than Rule 4354. After 2024, the NO_x emission limit in Rule 1117 is as stringent as that in Rule 4354. SJVAPCD Rule 4354 has other emissions limits for CO, VOC, and PM₁₀ which are not in Rule 1117.

²⁷ <http://www.aqmd.gov/docs/default-source/clean-air-plans/air-quality-management-plans/2022-air-quality-management-plan/final-2022-aqmp/appendix-vi.pdf?sfvrsn=12>

- SJVAPCD Rule 4692 Commercial Charbroiling

The control measure included in the 2018 PM2.5 Plan sought to achieve additional emission reductions from commercial under-fired charbroilers through an incentive-based approach to fund the installation of controls for commercial under-fired charbroilers within urban boundaries in hot-spot areas, with a future year regulatory requirement to encourage participation by Valley businesses. As of April 2023, only one restaurant had completed a retrofit installation of under-fired charbroiler control technology as part of the Valley's incentive program.²⁸

Rule 4692 was amended on June 21, 2018, but requirements to install controls for under-fired charbroilers were not included in the rule. The details of the rule requirements are explained in the Cooking-Commercial Charbroiling section of Existing and Potential Control Measures for Key PM Source Categories.

- SJVAPCD Rule 4901 Wood Burning Fireplace and Wood Burning Heaters

The control measure included in the 2018 PM2.5 Plan sought potential enhancements to its wood-burning curtailment program including lowering curtailment levels, enhanced levels of incentives, prohibiting wood-burning devices in new construction, enhanced outreach and education efforts, and new requirements for significant remodels of a fireplace or chimney.

Rule 4901 was amended on June 20, 2019. The details of the rule requirements are explained in the Residential Fuel Combustion – Wood Combustion – Wood Stoves section of Existing and Potential Control Measures for Key PM Source Categories.

- SJVAPCD Rule 4352 Solid Fuel-Fired Boilers, Steam Generators and Process Heaters

Rule 4352 limits NOx and CO emissions from any boiler, steam generator or process heater that is fired on solid fuel including municipal solid waste (MSW), biomass, and other solid fuels.

Rule 4352 was amended on December 16, 2021 to lower NOx limits to 110 ppm on MSW and 65 ppm on biomass and all others, averaged over 24-hours, on and after January 1, 2024. South Coast AQMD Rule 1146 sets a NOx emission limit at 40 ppm on any non-gaseous fueled unit, averaged over 15 minutes, which is more stringent than the NOx limits set in Rule 4352.

- SJVAPCD Rule 4550 Conservation Management Practices (CMP)

Rule 4550, adopted in 2004, targets fugitive particulate emissions from agricultural operations (e.g., tillage practices, land preparation activities, etc.) to bring the Valley into attainment of the PM10 NAAQS. San Joaquin Valley APCD committed to evaluate the feasibility and effectiveness of control measures to achieve additional PM2.5 emission reductions from tilling and other land

²⁸ Email from Kyle Matsumura, SJVAPCD on April 17, 2023

preparation activities based on the research and through additional incentives under Rule 4550. However, there have been no recent amendments to Rule 4550 that would trigger reassessment of the rule provisions as they relate to those in South Coast AQMD rules.

South Coast AQMD Rule 403 aims to reduce the amount of PM entrained in the atmosphere as a result of man-made fugitive dust sources by requiring actions to prevent, reduce or mitigate fugitive dust emissions. Rule 1186 further reduces PM emissions from livestock operations.

- SJVAPCD Rule 4702 Internal Combustion Engines

Rule 4702 applies to any internal combustion engine (ICE) rated at 25 bhp or greater and limits NOx, CO, VOC, and SOx emissions from applicable units including agricultural engines. In the 2018 PM2.5 Plan, SJVAPCD sought to further reduce NOx emissions from both agricultural and non-agricultural ICEs to the extent that such controls are technologically and economically feasible. Rule 4702 was amended on August 19, 2021 to establish emission limits for two engine ratings – one rated at least 25 bhp and up to 50 bhp and the other greater than 50 bhp. Stationary engines rated at up to 50 bhp must meet applicable requirements and emission limits specified in 40 CFR 60 Subparts IIII and JJJJ. Engines rated at greater than 50 bhp have separate emission limits by ignition type. Spark-ignited engines used in Agricultural Operations (AO) are required to meet 11 ppm NOx for rich-burn by 12/31/2023 and 43 ppm NOx for lean-burn engines by 12/31/2029 or 12 years after engine installation, whichever comes later. Non-AO spark-ignited engines are required to meet as low as 11 ppm NOx for both rich-burn and lean-burn engines with a full implementation date of 12/31/2023. South Coast AQMD Rule 1110.2 applies to all stationary and portable engines over 50 bhp and requires an 11 ppm NOx limit.

Plumas County, CA

Plumas County is part of the Northern Sierra AQMD. Staff did not identify any control measures to incorporate into the 2012 annual PM2.5 BACM analysis.

Imperial County, CA

South Coast AQMD staff reviewed Imperial County APCD's 2018 PM2.5 Plan and found no control measures that can potentially be incorporated into the 2012 annual PM2.5 BACM analysis.²⁹

Allegheny County, PA

Pennsylvania Department of Environmental Protection (PADEP) submitted the Allegheny County Area PM2.5 Plan³⁰ on September 30, 2019, on behalf of Allegheny County Health Department (ACHD), in order to meet the applicable CAA requirements for the 2012 annual PM2.5 NAAQS. U.S. EPA approved most

²⁹ <https://apcd.imperialcounty.org/wp-content/uploads/2020/01/2018-IC-PM25SIP.pdf>

³⁰ <https://downloads.regulations.gov/EPA-R03-OAR-2020-0157-0004/content.pdf>

required elements of the Allegheny County Area PM_{2.5} Plan, except for the contingency measures element of the plan, which U.S. EPA conditionally approved.³¹ Staff reviewed the RACM analysis³² and found the following measures to be potentially applicable to this BACM analysis.

- Commercial Cooking

Allegheny County has no existing control requirements for commercial cooking but evaluated HEPA filters for under-fired charbroilers as a technologically feasible emission control technology. The estimated cost-effectiveness was \$16,348 per PM_{2.5} ton reduced, and full implementation was anticipated to take 5 years. South Coast AQMD staff evaluated requiring the installation of fabric filters and other control technology for under-fired charbroilers in the Control Measure Assessment section.

- Fuel Combustion (Residential Wood)

Allegheny County has programs in place for residential wood stove and fireplace use, including wood stove change-out and “bounty” programs to replace existing wood stoves with new EPA-certified wood stoves, and a fireplace conversion program that offers discounts for fireplace inserts. The sale, installation, or purchase of non-Phase 2 outdoor wood-fired boilers is prohibited after May 31, 2011. An outdoor “no burn” policy is also in place when Air Quality Action Days are predicted.

Allegheny County noted in its analysis that some communities have required the removal and destruction of old wood stoves upon the sale of a home (e.g., Mammoth Lakes, CA; Washoe County, NV; and Jacksonville, OR). South Coast AQMD evaluates requiring replacement or removal of old wood-burning devices upon the sale or transfer of a property as discussed in the Control Measure Assessment section.

- Fugitive Dust

Dust suppressant applications are currently required at various locations within Allegheny County. Technologically feasible control measures include paving unpaved roads and unpaved parking lots and prohibiting the construction of new unpaved roads. Based on 80 percent rule penetration with unpaved roads representing 24 percent of the fugitive dust inventory, 0.19 tpd of PM_{2.5} emission reductions were estimated with this analysis. Cost-effectiveness was calculated based on SJVAPCD Rule 8061 to range between \$2,450 and \$6,725 per PM_{2.5} ton reduced and full implementation was anticipated one year after rule enactment.

South Coast AQMD Rule 1186 regulates vehicle trips on paved and unpaved public roads and at livestock operations and requires different control methods including certified street sweepers,

³¹ 86 FR 26388

³² <https://downloads.regulations.gov/EPA-R03-OAR-2020-0157-0014/content.pdf>

chemical stabilizers, and dust suppressants to reduce fugitive PM₁₀ emissions from roads. Between 1998 and 2006, Rule 1186 required annual treatment of unpaved public roads by either paving at least 1 mile of such roads, applying chemical stabilizer to 2 miles of such roads, or limiting vehicle speeds at 15 mph and/or installing speed bumps every 500 ft on 3 miles of such roads. Maintenance is required for chemically stabilized unpaved roads, but no such maintenance is required for paved roads. Paving unpaved public or private roads with maintenance of existing paved roads and prohibiting construction of new unpaved roads within urban areas is a potential control measure and the feasibility is assessed in the Control Measure Assessment section.

Step 2 – U.S. EPA’s Technical Support Documents

Newly adopted/amended rules to be incorporated into the California SIP have to be submitted for U.S. EPA’s review and approval. U.S. EPA prepares Technical Support Documents (TSDs) that review the State’s submittals of rules to be approved in the SIP, outline the CAA requirements for U.S. EPA to approve such submittal, and provide evaluation and recommendation for action on the State’s submittals. TSDs include U.S. EPA’s suggestions for future rule revisions that could be considered as potential control measures. In the 2016 AQMP, U.S. EPA’s TSDs finalized by December 2015 were reviewed as part of the 2016 AQMP BACM demonstration. Staff identified the following TSDs that have been issued since the 2016 AQMP:

- Rule 1111 (Reduction of NO_x Emissions from Natural Gas-Fired, Fan Type Central Furnaces; Approved March 29, 2016)
- Rule 1118 (Control of Emissions from Refinery Flares; Approved September 22, 2022)
- Rule 1118.1 (Control of Emissions from Non-Refinery Flares; Approved December 19, 2022)
- Rule 1147 (NO_x Reductions from Miscellaneous Sources; Approved December 28, 2016)
- Rule 1153.1 (Emissions of Oxides of Nitrogen from Commercial Food Ovens; Approved December 28, 2016)
- Rule 1168 (Adhesives and Sealant Applications; Approved February 24, 2021)

Of these TSDs, Rules 1118, 1118.1, and 1153.1 contained suggested rule amendments by U.S. EPA.

Below are U.S. EPA’s TSD recommendations for SIP-approved South Coast AQMD Rule 1118.

“Rule 1118 subparagraph (j) provides the Executive Officer the authority to approve another ASTM method. Without further specificity regarding how this authority will be exercised, it could functionally allow for a revision of the SIP without complying with the process for SIP revisions required by the CAA. As a result, this undermines the enforceability of the submission, constitutes a SIP deficiency, and conflicts with CAA Section 110. To resolve this deficiency, we recommend that Rule 1118 be amended to remove this clause, or the district would include sufficient detail in advance of the time of approval of the SIP provision, showing that the exercise of the director’s

discretion will not interfere with other CAA requirements. Another resolution would be for the language to include a requirement that the alternative test method also is federally approved.”

Rule 1118 was amended on January 6, 2023 to address U.S. EPA’s concern and now includes CARB and U.S. EPA approval for ASTM standards. Below are U.S. EPA’s TSD recommendations for SIP-approved South Coast AQMD Rule 1118.1.

“The following revisions are not currently the basis for rule disapproval, but are recommended for the next time the rule is amended. In Section (d)(3)(B), an owner or operator shall submit a Notification of Intent to the Executive Officer when the flare or flare station’s annual percent capacity is greater than the applicable threshold for two consecutive calendar years. According to the Final Staff Report after July 1st, 2024, most, if not all, of the flares and flare stations would have made changes to meet the thresholds listed in the rule; and ideally any exceedance of the thresholds in the rule would be uncommon. Therefore, we are recommending that in the future, after one calendar year (instead of the current 2 years) that a flare or flare station’s annual percent capacity is greater than the applicable threshold listed in Table 2 – Annual Capacity Thresholds, the owner or operator shall submit a Notification of Intent to the Executive.

In South Coast AQMD Rule 1118, BAAQMD Rule 12-11, BAAQMD Rule 12-12, SBCAPCD Rule 359, and SJVAPCD Rule 4311 there is a requirement that a pilot flame or an automatic ignition is operating at the time when combustible gases are vented through the flare. The NESHAP Subpart A for General Provisions § 60.18- General control device and work practice requirements and NSPS Subpart A for General Provisions § 63.11 – Control device and work practice requirements, both require flares to have a pilot flame present during flaring. Even though pilot flames or auto ignition are present during flaring in the non-refinery flares in South Coast, we recommend that this requirement be added during the next rule amendment.”

Below are U.S. EPA’s TSD recommendations for SIP-approved South Coast AQMD Rule 1153.1.

“In section (c)(1), consider adopting a lower NO_x limit similar to the limit in San Joaquin Valley APCD Rule 4309 for the next time rule revision. San Joaquin Valley APCD Rule 4309 (Dryers, Dehydrators, and Ovens) contains a NO_x limit of 4.3 ppm at 19 percent oxygen for applicable units and is lower than the NO_x emission limit of 60 ppm at 3 percent oxygen (6.5 ppm at 19 percent oxygen) in Rule 1153.1 for units run at temperatures greater than 500 °F.”

Rule 1153.1 was amended on August 4, 2023, to address as part of the Regional Clean Air Incentives Market (RECLAIM) transition to a command-and-control regulatory structure. The recently amended rule established new Best Available Retrofit Control Technology (BARCT) limits for all commercial food ovens which includes dryers, smokehouses, cooking ovens, and coffee roasters. The rule also establishes new zero- emission limits for several categories. All applicable units are now required to meet a NO_x limit of 30 ppm at 3 percent oxygen regardless of operating temperature. In addition, several categories are required to meet a zero- emission limit at a future date. The recent rule amendments address U.S. EPA’s concerns regarding the NO_x limit since the NO_x limits for Rule 1153.1 are more stringent than those in San Joaquin Valley APCD’s Rule 4309.

Based on the above recommendations, and considering recent rule amendments, staff did not identify any new PCMs that could be considered in this analysis.

Step 3 – Potential Control Measures from Previous Plans

BACM/BACT is a moving target that changes over time as new technologies and products become feasible and cost-effective. For this BACM demonstration, therefore, PCMs from previous plans were reassessed considering the latest emissions inventory, current state of technology, and cost data. Staff revisited the BACM evaluation for the 2012 annual PM_{2.5} standard and the Reasonably Available Control Measures (RACM) evaluation for the 2015 8-hour ozone standard in the 2016 and 2022 AQMPs, respectively. From the 2016 AQMP, staff identified several PCMs that were either rejected as infeasible or were otherwise not included and adopted as control measures. From the 2022 AQMP, one potential RACM that was determined to be technologically infeasible was reassessed. All remaining measures were not applicable based on precursor demonstrations, were incorporated into rule requirements, or were included as commitment in the plan. Precursor demonstrations presented in Appendix VI of this Plan evaluated the contribution of individual PM_{2.5} precursor to ambient PM_{2.5} levels. According to U.S. EPA's guidance and their implementation rule, the precursors with less than significant contribution are allowed to exclude exempted from control strategy analysis. As VOC and SO_x are not significant precursors in this PM_{2.5} Plan, VOC and SO_x measures were not considered. Table III-3 provides a summary of all measures that were reviewed and an explanation why some measures were omitted in this BACM demonstration.

The following section provides short descriptions of the control measures that were reconsidered in this analysis. A detailed analysis for each control measure is included in the Control Measure Assessment section.

**TABLE III-3
SUMMARY OF PCMS REVIEWED IN THE 2016 AND 2022 AQMPs**

PCM	Applicable AQMP	Reconsidered in this BACM demonstration?	If not, reason why
Lowering NO _x emission limits for boilers, steam generators, and process heaters	2022 AQMP	Yes, PCM 15	
VOC Emission Reductions from Cooling Towers	2022 AQMP	No	Precursor demonstration for VOC
Lowering NO _x emission limit for commercial food ovens	2022 AQMP	No	Rule 1153.1 was amended on 8/4/2023 to address this PCM

PCM	Applicable AQMP	Reconsidered in this BACM demonstration?	If not, reason why
Additional Enhancement in Reducing Existing Residential Building Energy Use	2016 and 2022 AQMPs	No	Included in control strategy; see ECC-03
Lowering VOC Emission Limit for Gasoline Bulk Terminals	2016 and 2022 AQMPs	No	Precursor demonstration for VOC
Lowering VOC Emission Limit for Auto and Light-Duty Truck Assembly	2016 and 2022 AQMPs	No	Precursor demonstration for VOC; Rule 1115 amended in March 2022 to address this PCM
Lowering VOC Limits Interior Body Sprays for Metal Container, Closure, and Coating Operations	2016 and 2022 AQMPs	No	Precursor demonstration for VOC
Co-Benefits from Existing Residential and Commercial Building Energy Efficiency Measures	2016 and 2022 AQMPs	No	Included in control strategy; see ECC-02
Co-Benefit Emission Reductions from GHG Programs, Policies, and Incentives	2016 and 2022 AQMPs	No	Included in control strategy; see ECC-01
Emission Reductions from Replacement with Zero or Near-Zero NOx Appliances in Commercial and Residential Applications	2016 AQMP	Yes, PCM 1	
Emission Reductions from Cooling Towers	2016 AQMP	Yes, PCM 3	
Ammonia Emission Reductions from NOx Controls	2016 AQMP	No	Ammonia slip limits are established through permitting. Additionally, this measure is included in the control strategy; see BCM-05.

PCM	Applicable AQMP	Reconsidered in this BACM demonstration?	If not, reason why
Further Emission Reductions from Agricultural, Prescribed, and Training Burning	2016 AQMP	Yes, PCM 5	
Emission Reductions from Non-Refinery Flares	2016 AQMP	No	Rule 1118.1 was adopted on January 4, 2019 to address this PCM
Further Emission Reductions from Commercial Cooking	2016 AQMP	Yes, PCM 6	
Further Emission Reduction from Fugitive Dust Sources	2016 AQMP	Yes, PCM 7	
Further Emission Reductions from Wood Burning Fireplaces and Wood Stoves	2016 AQMP	Yes, PCM 8	
Emission Reductions from Greenwaste Composting	2016 AQMP	Yes, PCM 9	
Emission Reduction of PM from Asphalt Manufacturing	2016 AQMP	Yes, PCM 10	
Emission Reduction of PM from Wood Pulp and Paper	2016 AQMP	Yes, PCM 11	
Emission Reduction of VOC and NO _x Through Reformation and Process Modification for Cutback Asphalt	2016 AQMP	Yes, PCM 12	
Emission Reductions from Manure Management Strategies	2016 AQMP	Yes, PCM 13	

Emission Reductions from Replacement with Zero or Near-Zero NO_x Appliances in Commercial and Residential Applications

This measure sought emission reductions through a zero NO_x standard for new commercial and residential water and space heaters. It has been updated based on recent amendments to BAAQMD Regulation 9 Rules 4 and 6. The measure examines the feasibility of introducing zero NO_x emission limits following a phased approach that depends on the appliance size and type.

Emission Reductions from Cooling Towers

This measure sought reductions of PM from industrial cooling towers by requiring use of the latest drift eliminator technologies. The control measure would reduce PM_{2.5} emissions from evaporative cooling towers by requiring all units to upgrade their drift eliminators to more efficient drift eliminators that keep drift losses to less than 0.001 percent of the recirculating water flow rate. Newly constructed cooling towers have demonstrated an ultra-low drift rate of 0.0005 percent. This drift rate has been achieved in practice and could be considered BACT for new construction. Although efficiency improvements are achievable through use of the newer drift eliminators, the proportion of PM_{2.5} in the overall drift is fairly small compared to the PM₁₀ fraction (PM_{2.5} estimated at ~3 percent of PM₁₀).

Further Emission Reductions from Agricultural, Prescribed, and Training Burning

This control measure sought further PM emission reductions from certain categories of open burning including agricultural and prescribed (e.g., forestry service) burning activities. Reducing agricultural burning by incentivizing alternatives (e.g., chipping/grinding or composting) is possible. Additional considerations were given to aligning burn prohibitions with any potential changes to the Rule 444 no burn day provisions which could further reduce open burning emissions during peak PM_{2.5} episodes. Burning alternatives such as chipping/grinding or composting are widely available in the Basin.

Further Emission Reductions from Commercial Cooking

South Coast AQMD Rule 1138 regulates VOC and PM emissions from restaurant operations by requiring the installation of flameless catalytic oxidizers, or equivalent control devices, to chain-driven charbroilers. Although under-fired charbroilers are another source of emissions from restaurant operations, no cost-effective control technology was identified for this type of equipment at the time of rule adoption. Staff continued efforts to find cost-effective and technologically feasible controls for the restaurant industry. Retrofitting control devices at existing restaurants may require a complete system overhaul including fire suppression, ventilation, and electrical components. The 2016 AQMP specified that this measure would serve as an attainment contingency measure. Therefore, it was not included in the attainment control strategy.

Further Emission Reduction from Fugitive Dust Sources

South Coast AQMD Rule 1186 establishes requirements to prevent material from being deposited on roadways and requires local jurisdictions to procure certified street sweeping equipment. Under Rule 1186, certified street sweepers must have a pick-up efficiency greater than or equal to 80 percent and achieve entrained PM₁₀ emissions of less than or equal to 200 mg/m. This control measure sought further PM emission reductions from entrained road dust, one of the major direct PM_{2.5} sources due to the large number of roadways and high traffic volumes in the region. Most cities in the Basin have regular street sweeping schedules so the emission reduction from mandating street sweeping frequency is expected to be minimal.

Further Emission Reductions from Wood-Burning Fireplaces and Wood Stoves

Rule 445 is designed to reduce PM emissions from wood-burning devices. The rule establishes requirements for the sale, operation, and installation of wood-burning devices. This control measure sought to include a provision that would apply to uncertified wood-burning devices during the sale or transfer of property similar to that in SJVAPCD Rule 4901.

Lowering the Curtailment Threshold in Rule 445

Under South Coast AQMD Rule 445, Basin-wide curtailment is mandatory when PM_{2.5} concentrations are forecast to exceed 29 µg/m³ from November through February. The South Coast AQMD curtailment threshold applies to all solid fuel devices, including wood-based residential cooking devices. This control measure sought to evaluate the feasibility of lowering the curtailment threshold to achieve further emission reductions.

Emission Reduction of PM from Asphalt Manufacturing

This control measure was based on U.S. EPA's 2012 version of the Menu of Control Measures.³³ The measure estimated a control efficiency of 99 percent in an asphalt manufacturing facility equipped with a fabric filter or baghouse placed in parallel inside of an enclosure. Asphalt manufacturing in the South Coast AQMD is currently regulated under Rule 1157 and Rule 1155, which require the use of filters. Rule 1157 targets all aggregate and related operations but does not require enclosure for all transfer points and activities. However, Rule 1155 regulates all baghouses (including those at asphalt manufacturing facilities), except for those with a filter area less than 100 sq. ft. and requires no visible emissions at any time except for start-up and shutdown. Enclosures and baghouses are generally technologically feasible. The standard (0.01 gr/dscf) for baghouses in asphalt manufacturing facilities was set forth in Rule 1155 and was fully implemented in 2013.

³³ <https://www3.epa.gov/ttn/naaqs/pdfs/MenuOfControlMeasures.pdf>

Emission Reduction of PM from Wood Pulp and Paper

This control measure was based on U.S. EPA's 2012 version of the Menu of Control Measures.³⁴ The measure estimated a control efficiency of 95 percent in wood pulp and paper facilities equipped with dry/wet electrostatic precipitators (ESPs). Currently, there are five permitted recycled paper and paperboard manufacturing facilities in South Coast AQMD. An electrostatic precipitator (ESP) is predominantly used to control PM emissions from Kraft recovery furnaces used at paper manufacturing facilities that process virgin raw materials. For the recycled material manufacturing facilities, little or no PM is emitted from the pulp dryer.

Emission Reductions from Greenwaste Composting

This control measure sought emission reductions of VOC and NH₃ from composting of greenwaste, foodwaste, and agricultural waste streams. Evaluated control approaches included improved emissions characterization via inventory and emission factor development, anaerobic digestion, pollution prevention technology, and restrictions for direct applications of uncomposted, chipped or ground non-curbide greenwaste to public lands.

Reformulation and Process Modification for Cutback Asphalt

The measure sought to examine the feasibility of requiring warm-mix asphalt. Warm-mix asphalt would reduce natural gas use by an estimated 20 to 25 percent from reduced processing and transportation temperatures compared to hot-mix asphalt. Although the reduction in natural gas use was found to reduce NO_x emissions, studies revealed mixed results for VOC emissions from warm-mix compared to hot-mix asphalt.

Emission Reductions from Manure Management Strategies

This measure sought NH₃ emission reductions by lowering the applicability thresholds in Rule 223 to be as stringent as those in SJVAPCD Rule 4750 for confined animal facilities. It also explored the feasibility of additional mitigation measures for livestock waste to further reduce NH₃ emissions.

Lowering Emission Limits for Boilers, Steam Generators, and Process Heaters

This measure is derived from the 2022 AQMP RACM demonstration and is based on the more stringent NO_x limits for boilers, steam generators, and process heaters greater than or equal to 5 MMBtu/hr in SJVAPCD Rules 4306 and 4320 compared to those in Rule 1146. For details on the emission limits, refer to the discussion regarding Rules 4306 and 4320 in Step 3 - Control Measures in Other Nonattainment Areas.

³⁴ Ibid

Step 4 – U.S. EPA’s Menu of Control Measures

The Menu of Control Measures (MCM)³⁵ compiled by the State and Local Programs Group within U.S. EPA’s Office of Air Quality Planning and Standards, was developed to provide information useful in the development of local emission reduction and NAAQS SIP scenarios. U.S. EPA’s MCM provides a broad listing of emission reduction measures to assist states in identifying and evaluating potential measures. The measures are based in part on the results of a literature review of the current and proposed measures of various air quality agencies, including CARB, California air districts, the Ozone Transport Commission, the Lake Michigan Air Directors Consortium, and others. For each source category, one or more emission reduction measures, the respective control efficiency, and cost effectiveness are provided.

At the time of writing, the MCM published on September 22, 2022 was the latest version available and it was therefore selected for this analysis. Staff reviewed the control measures for point and nonpoint sources of PM_{2.5}, NH₃, and NO_x. The review identified four measures from the MCM that exceeded the requirements of existing rules, were not included in the 2022 AQMP, and were not otherwise identified as part of this BACM demonstration. The identified measures are as follows:

- Increasing the fuel moisture for prescribed burns
- Requiring electrostatic precipitators, fabric filters, and scrubbers for various industrial and commercial processes
- Requiring Selective Catalytic Reduction (SCR) of NO_x for incinerators
- Requiring extended absorption to reduce NO_x from nitric acid manufacturing

Proposed Rule 1165, Control of Emissions from Incinerators, is under development and will include NO_x emission limits for incinerators consistent with the control efficiency specified in the MCM. There are no nitric acid manufacturing facilities located in the South Coast Air Basin and thus this measure was not evaluated. Staff evaluated the remaining control measures for potential emission reductions in the Basin and the assessment can be found in the Control Measure Assessment section.

Step 5 – U.S. EPA’s Guidance Documents

In March 2013, the U.S. EPA revised its document “*Strategies for Reducing Residential Wood Smoke*”³⁶ to provide new information and tools to help state, tribal, and local air officials reduce fine particle pollution from residential wood smoke. The document provides a comprehensive list of strategies to help identify appropriate wood smoke reduction measures. A combination of regulatory, voluntary, and educational strategies is encouraged to ensure a successful wood smoke program with measurable emission reductions. U.S. EPA recommends that each area determine the most appropriate measures given the

³⁵ <https://www.epa.gov/air-quality-implementation-plans/menu-control-measures-naaqs-implementation>

³⁶ <https://www.epa.gov/sites/default/files/documents/strategies.pdf>

nature and extent of their problem. Table III-4 is a list of regulatory options outlined in the guidance document, and the corresponding control strategies (where applicable) in South Coast AQMD.

TABLE III-4
U.S. EPA LIST OF REGULATORY OPTIONS FOR REDUCING RESIDENTIAL WOOD SMOKE AND
SOUTH COAST AQMD CURRENT CONTROL STRATEGIES

U.S. EPA Suggested List of Regulatory Options	South Coast AQMD Control Strategies
1. Wood-Burning Curtailment Programs	Rule 445 enacts a mandatory winter wood-burning curtailment when PM _{2.5} concentrations are forecasted to exceed 29 µg/m ³ .
2. Opacity and Visible Emission Limits	South Coast AQMD Rule 401 does not have a "no visible emissions" requirement. Instead, Rule 401 requires the Ringelmann Chart No. 1 or an equivalent (10 percent) opacity limit.
3. Wood Moisture Content	Rule 445 requires a commercial firewood seller to only sell seasoned wood (≤20 percent moisture) from July 1 through the end of February the following year.
4. Removal of Old Wood Stove Upon Resale of a Home	Currently, South Coast AQMD does not require the removal and destruction of old wood stoves upon the resale of a home. For further analysis of this regulatory option, refer to the discussion under Key PM Source Categories.
5. Require EPA Certification	For existing residential and commercial developments (additions, remodels, etc.), Rule 445 requires wood-burning devices sold or installed to be U.S. EPA certified or equivalent. Newly installed fireplaces must be gaseous-fueled or electric.
6. Ban the Use of Non-EPA-Certified Wood Stoves	Currently, South Coast AQMD does not prohibit the use of non-EPA certified wood stoves that have been installed in existing homes and businesses prior to the adoption of Rule 445. For further analysis of this regulatory option, refer to the discussion under Key PM Source Categories.
7. Restrictions on Wood-Burning Devices in New Construction	Rule 445 prohibits the installation of all wood-burning devices in new construction.
8. Hydronic Heater Rules	The use of hydronic heaters is very uncommon in South Coast AQMD; further restrictions on these devices would therefore not be expected to result in emission reductions.
9. Requirements for Wood-burning Fireplaces	For existing residential and commercial developments (additions, remodels, etc.), Rule 445 requires wood-burning devices sold or installed to be U.S. EPA certified or equivalent. Incentives are available to replace wood-burning devices with cleaner alternatives in some neighborhoods.

U.S. EPA Suggested List of Regulatory Options	South Coast AQMD Control Strategies
10. State/Tribal/Local Wood-Heating Emission Standards	U.S. EPA's New Source Performance Standards (NSPS) have the most stringent emission limit across the nation for residential wood heaters.
11. NSPS for New Residential Wood Heating Appliances	Rule 445 defines U.S. EPA certified heaters as those that comply with Title 40 Code of Federal Regulations, Part 60, Subpart AAA, March 16, 2015, or any subsequent revision. The NSPS for wood heating appliances are codified under this subpart.

In addition to the regulatory programs listed in Table VI-A-10, the South Coast AQMD has implemented the Healthy Hearths™ program that includes a comprehensive education and outreach effort to encourage the public to switch to cleaner, gaseous-fueled hearth products. An incentive program for cleaner hearth appliances is ongoing to encourage the public to switch to cleaner hearth products, including gaseous-fueled devices that are exempt from burning curtailments.³⁷ As part of the Healthy Hearths™ initiative, the “Check Before You Burn” program is designed to protect public health by reducing harmful wood smoke from residential wood-burning from November 1 through the end of February. Daily air quality forecast information can be found online on the South Coast AQMD’s “Check Before You Burn” map, through e-mail messages, or a toll-free number. Rule 445 also contains labeling requirements for commercial firewood or other wood-based fuel sellers to notify the public of South Coast AQMD’s Check Before You Burn program.

Summary of Potential Control Measures

After thorough review of the above listed sources, South Coast AQMD staff identified the following PCMs for stationary sources listed in Table III-5. The PCMs were assessed for technological and economic feasibility in the Control Measure Assessment section.

**TABLE III-5
POTENTIAL STATIONARY SOURCE CONTROL MEASURES**

#	Potential Control Measure	Target Pollutant	South Coast AQMD Current Control	Source of Information
1	Replacement with Zero NO _x Space and Water Heaters in Commercial and Residential Applications	NO _x	Rules 1111 and 1121	Step 1 – Other Districts’ Control Measures; Step 3 – Potential Control Measures from Previous Plans

³⁷ <http://www.aqmd.gov/home/programs/community/community-detail?title=wood-device-incentive-program>

#	Potential Control Measure	Target Pollutant	South Coast AQMD Current Control	Source of Information
2	Glass Melting and Sodium Silicate Furnaces	PM2.5	Rule 1117	Step 1 – Other Districts’ Control Measures
3	Cooling Towers	PM2.5	Not Applicable	Step 3 – Potential Control Measures from Previous Plans
4	Livestock Waste at Confined Animal Facilities	NH3	Rule 223	Step 1 – Other Districts’ Control Measures
5	Agricultural, Prescribed, and Training Burning	PM2.5	Rule 444	Step 3 – Potential Control Measures from Previous Plans
6	Commercial Cooking - Charbroilers	PM2.5	Rule 1138	Step 1 – Other Districts’ Control Measures Areas; Step 3 – Potential Control Measures from Previous Plans
7	Paved Road Dust	PM2.5	Rule 1186	Step 3 – Potential Control Measures from Previous Plans
8	Wood-Burning Fireplaces and Wood Stoves	PM2.5	Rule 445	Step 1 – Other Districts’ Control Measures; Step 3 – Potential Control Measures from Previous Plans
9	Organic Waste Composting	NH3	Rule 1133.3	Step 3 – Potential Control Measures from Previous Plans
10	Asphalt Manufacturing	PM2.5	Rule 1157	Step 3 – Potential Control Measures from Previous Plans
11	Wood Pulp and Paper	PM2.5	Not Applicable	Step 3 – Potential Control Measures from Previous Plans
12	Reformulation and Process Modification for Cutback Asphalt	NOx	Rule 1108	Step 3 – Potential Control Measures from Previous Plans
13	Unpaved Lots, Roads, and Shoulders	PM2.5	Rule 1186	Step 1 – Other Districts’ Control Measures; Step 4 – U.S. EPA’s Menu of Control Measures
14	Industrial and Commercial Combustion Processes	PM2.5	Not Applicable	Step 4 – U.S. EPA’s Menu of Control Measures
15	Lowering Emission Limits for Boilers, Steam Generators, and Process Heaters	NOx	Rule 1146	Step 3 – Potential Control Measures from Previous Plans

In addition to the above analyses, SCAG, CARB, and South Coast AQMD staff have completed the following analyses to meet the requirements of the CAA:

- BACM and MSM demonstrations conducted by CARB and SCAG for mobile sources and transportation control measures are included in Appendices III-B and IV-B, respectively.
- Cost-effectiveness analyses and schedules for implementation for each of the stationary source and mobile source control measures, if available, are provided in Chapter 4, and Appendix IV-A for South Coast AQMD's control measures and Appendix IV-B for CARB's control measures, respectively.

Conclusion

As required by the CAA and U.S. EPA's PM_{2.5} Implementation Rule, South Coast AQMD staff evaluated and analyzed a wide range of sources to develop a comprehensive list of PCMs. PCMs from the 2016 AQMP, potential RACM from the 2022 AQMP, attainment plans in other jurisdictions, rules and regulations implemented by other air districts, and multiple resources published by U.S. EPA were consulted. In general, South Coast AQMD's existing rules and regulations were found to require the most stringent level of control. There were, however, limited instances where rules could be strengthened to achieve further reductions. This resulted in the identification of 15 PCMs for which the technological and economic feasibility was assessed. A comprehensive assessment of all PCMs is presented in the next section of this Appendix.

CONTROL MEASURE ASSESSMENT

Introduction

The PCMs identified in the preceding section are evaluated to advance South Coast AQMD’s emission control strategies. A comprehensive feasibility analysis is conducted for all PCMs. Each measure is independently assessed to determine whether it can be considered as BACM, an additional feasible measure, or MSM while complying with U.S. EPA’s requirements.³⁸ U.S. EPA requires that BACM be adopted and the controls be partially or fully implemented within four years of reclassification to “serious” nonattainment. Since the South Coast Air Basin was reclassified effective December 2020, the area has until December 2024 to partially or fully implement BACM. If the analysis concludes that a measure cannot be feasibly implemented within this timeframe, it is reassessed as an additional feasible measure, or one that can be implemented by 2025, the statutory “serious” area attainment year. Finally, measures that cannot be implemented as either BACM or additional feasible measures are reassessed as potential MSM. While this analysis is allowed to consider technological and economic feasibility, U.S. EPA recommends that the analysis “apply more stringent criteria for determining the feasibility of potential MSM than that described for BACM and BACT.”³⁹ Furthermore, the feasibility analysis for potential MSM must consider the longer timeframe allowed for implementation (up to 4 years after the statutory “serious” area attainment date). For measures that cannot be feasibly implemented as MSM, a reasoned justification for rejecting the potential MSM is included.

The emissions inventories, emission reduction estimates, and cost-effectiveness are based on the best information available at this time. Quantified emissions and estimated reductions are based on a variety of data sources, including, but not limited to, the emissions inventory presented in Chapter 3 and Appendix I of this Plan, South Coast AQMD’s Annual Emissions Reporting program, archived equipment statistics obtained from South Coast AQMD’s past rulemaking, and data libraries of public energy policy and planning agencies and utilities (e.g., California Public Utilities Commission, California Energy Commission, Southern California Edison, etc.). Staff commits to refine these estimates as new information becomes available during subsequent rulemaking and control measure implementation.

Potential Control Measure 1 - Emission Reductions from Replacement with Zero NOx Space and Water Heaters in Commercial and Residential Applications

Target Pollutant

NOx

Synopsis

This control measure, based on recent amendments to BAAQMD Regulation 9, seeks NOx emission reductions through a zero NOx standard for new commercial and residential water and space heaters. Zero NOx requirements would follow a phased approach that depends on the appliance size and type. This control measure applies to manufacturers, distributors, sellers, installers and purchasers of these appliances.

Potential Emission Reduction

The 2030 baseline inventory is 12.22 tpd of NOx for this source category.

Estimated emission reductions are 2.58 tpd by 2030.

Technological Feasibility

There are currently a wide variety of zero NOx electric heat pump water heaters and heat pump space conditioning (heating and cooling) systems available on the market that operate on a 240-volt circuit.^{40,41}

A limited number of space and water heaters are also available for residences that only have 120-volt service (see Table III-6). Manufacturers are actively developing new heat pump systems and it is therefore expected that the number of new models will increase substantially over the next several years.

⁴¹ Energy Star Certified Central Heat Pumps. <https://www.energystar.gov/productfinder/product/certified-central-heat-pumps/results>

**TABLE III-6
COMMERCIALLY AVAILABLE 120-VOLT SPACE AND WATER HEATERS**

Manufacturer	Model	Type
Pioneer	WYT012ALFI19RL, WYT009ALFI19RL (and others)	Space heater
Hessaire	H12E1	Space heater
LG	LS120HXV2, LS090HXV2	Space heater
Mitsubishi	MZ-JP12WA, MZ-JP09WA	Space heater
Fujitsu	9RL2, 12RL2	Space heater
General Electric	AS09CRA, AS12CRA	Space heater
Senville	LETO series	Space heater
MRCOOL	DIY-12-HP-115B	Space heater
LBG Products	LBH12ATO, LBH09ATO	Space heater
AUX	Inverter series	Space heater
Daizuki	DXTH12C416-20	Space heater
Nyle Water Heating Systems	E8	Water heater
Rheem	ProTerra (Plug-In)	Water heater

Economic Feasibility

A comprehensive cost analysis for residential and commercial space and water heating appliances was conducted as part of the 2022 State SIP Strategy, Appendix A: Economic Analysis.⁴² These measures were determined to be economically feasible with a cost-effectiveness value of \$496,600/ton NO_x.

Summary Table

Type of Analysis	Emission Reduction	Technological Feasibility	Economic Feasibility	Feasible Measure
BACM/BACT	2.58 tpd of NO _x by 2030	No	No	No
Additional feasible measure		No	No	No
MSM		Feasible Yes	Feasible Yes	Yes

For the purposes of satisfying MSM, this measure is included in CARB's commitment as the Zero-Emission Standard for Space and Water Heaters with implementation beginning January 1, 2030. Independent of MSM, South Coast AQMD's control measures BCM-01 and BCM-02, which overlap with CARB's measure, are also included in the PM_{2.5} Plan since these measures will implement before CARB's measure and also

⁴² https://ww2.arb.ca.gov/sites/default/files/2022-09/2022_State_SIP_Strategy_App_A.pdf

target accelerated turnover of appliances through incentives. A comparison of South Coast AQMD control measures and BAAQMD rules targeting space and water heaters is shown in Table III-7. In many cases, South Coast AQMD's proposed rules implement zero emission requirements ahead of BAAQMD's rules.

**TABLE III-7
COMPARISON OF SOUTH COAST AQMD CONTROL MEASURES AND BAAQMD RULES
REGULATING NOX EMISSIONS FROM SPACE AND WATER HEATERS**

Category	South Coast AQMD BCM-01 and BCM-02 Proposed Control*	BAAQMD Rules 9-4 & 9-6
Residential Space Heating (< 175,000 Btu/hr)	(1) 0 ng/J by 1/1/2029 6 (new buildings) where feasible, and 1/1/2028 (existing buildings) 7 ng/J where not (2) incentivize zero emission technologies with a focus on electric panel upgrades needed for older homes	0 ng/J by 1/1/2029
Commercial Space Heating (> 175,000 Btu/hr)	<u>0 ng/J by 1/1/2026 (new buildings) and 1/1/2028 (existing buildings)</u> —	---
Residential Water Heating (< 75,000 Btu/hr)	(1) <u>0 ng/J by 1/1/2026 (new buildings) and 1/1/2028 (existing buildings)</u> 0 ng/J by 1/1/2029 where feasible, 5 ng/J where not (2) incentivize zero emission technologies with a focus on electric panel upgrades needed for older homes	0 ng/J by 1/1/2027
Commercial Water Heating (≥75,000 Btu/hr and ≤2 MMBtu/hr)	<u>0 ng/J between 1/1/2026 and 1/1/2033 following a —phased approach that depends on the size and temperature of the heater</u>	0 ng/J by 1/1/2031

*Implementation dates are based on preliminary rule concepts and are subject to change. Refer to: <https://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/1111-and-1121/par-1111-and-1121-wgm4-april-2024.pdf?sfvrsn=14> and <https://www.aqmd.gov/docs/default-source/Agendas/ssc/ssc-agenda-3-15-2024.pdf>.

Potential Control Measure 2 – Emission Reductions from Glass Melting and Sodium Silicate Furnaces

Target Pollutant

PM2.5

Synopsis

In the South Coast Air Basin, there are two facilities that operate a total of two container glass melting furnaces and one sodium silicate furnace. These furnaces are subject to NO_x and SO_x emission limits in South Coast AQMD Rule 1117; however, Rule 1117 does not enforce PM₁₀ emission limits unlike SJVAPCD Rule 4353, which sets a limit at 0.20 lb/ton for container glass furnaces. A significant fraction of PM₁₀ emissions from these facilities is emitted as PM_{2.5}. This measure therefore seeks to evaluate the feasibility of requiring glass melting and sodium silicate furnaces to meet PM₁₀ emission limits.

Potential Emission Reduction

The 2030 baseline inventory is 0.0641 tpd of PM_{2.5} for this source category.

Potential emission reductions are 0 tpd.

Technological Feasibility

It is technologically feasible to achieve the emission limit specified in SJVAPCD Rule 4353 for gas-fired container glass melting furnaces. The feasibility is further supported by an identical emission limit enforced at the federal level.⁴³ However, there are no applicable federal emission limits for sodium silicate furnaces and the PM₁₀ emission limits in SJVAPCD Rule 4353 also do not apply to sodium silicate furnaces.

Economic Feasibility

It is economically feasible to achieve a PM₁₀ emission limit of 0.20 lb/ton for container glass melting furnaces.

Summary Table

Type of Analysis	Emission Reduction	Technological Feasibility	Economic Feasibility	Feasible Measure*
BACM/BACT	0 tpd PM _{2.5}	<u>Yes</u> Feasible	<u>Yes</u> Feasible	No
Additional feasible measure		<u>Yes</u> Feasible	<u>Yes</u> Feasible	No
MSM		<u>Yes</u> Feasible	<u>Yes</u> Feasible	No

⁴³ CFR Title 40, Chapter I, Subchapter C, Part 60, Subpart CC

* While this measure is technologically and economically feasible in practice it is currently infeasible due to other considerations.

Other Considerations

Staff reviewed source test results, conducted between 2018 and 2022, for the two container glass furnaces and all source tests measured an emission factor ≤ 0.20 lb PM/per ton (see Table III-8). Since actual emission rates comply with both SJVAPCD Rule 4353 and the federal limit, no further emission reductions would occur by incorporating a PM₁₀ emission limit for container glass furnaces in Rule 1117. Therefore, staff concludes that this control measure is not warranted.

**TABLE III-8
PM SOURCE TEST RESULTS FOR GLASS MELTING FURNACES
AT OWENS-ILLINOIS (FACILITY ID: 7427)**

Test Date	Furnace	PM Result (lb PM/ton produced)
11/9/2022	B	0.08

11/16/2018	C	0.06

Potential Control Measure 3 - Emission Reductions from Cooling Towers

Target Pollutant

PM_{2.5}

Synopsis

This measure would seek reductions of PM_{2.5} from industrial cooling towers by requiring operators to use the latest drift eliminator technologies. Reducing PM_{2.5} emissions from cooling towers could involve a simple upgrade: requiring all units to install more efficient drift eliminators. These upgraded eliminators would ensure that drift losses are kept to a minimum, specifically less than 0.001 percent of the re-circulating water flow rate. This not only reduces emissions but also leads to significant water savings. Currently, industrial cooling towers are required to submit information on total dissolved solids (TDS) via a registration filing under Rule 222 - Filing Requirements for Specific Emission Sources Not Requiring a Written Permit Pursuant to Regulation II. The information that has been collected would be evaluated during the rule development process and used to allow PM_{2.5} emissions to be calculated. Appendix IV-A of the 2016 AQMP contained a potential control measure to reduce cooling tower PM emissions but concluded that PM_{2.5} emission reductions were not cost-effective. The 2016 AQMP did, however, include Control Measure BCM-02 (Emission Reductions from Cooling Towers) so this PM_{2.5} Plan also includes a control measure, BCM-13, that proposes a further evaluation of cooling tower PM_{2.5} emissions.

In addition to the high costs, a recent study conducted for the California Energy Commission (CEC) found that cooling towers may act as scrubbers for surrounding areas and emit negative emissions of coarse particulate matter (between 2.5 and 10 microns), and potentially have the same effect on PM_{2.5} emissions.⁴⁴ The study also found that drift eliminators may vastly outperform their efficiency specifications. These findings should be examined prior to implementing controls.

Potential Emission Reduction

Potential emission reduction is to be determined.

Technological Feasibility

Newly constructed cooling towers have demonstrated ultra-low drift rates of 0.0005 percent. However, overall drift eliminator efficiencies and cooling tower effects on emissions in surrounding areas should be further examined prior to implementing controls.

Economic Feasibility

The 2016 AQMP included a cost estimate of \$1.37 million to retrofit a local refinery cooling tower with a high efficiency drift eliminator. The reduction in total PM, PM₁₀, and PM_{2.5} was also previously estimated at approximately 173, 11, and 0.4 tons per year, respectively. Cost effectiveness for BCM-02 in the 2016 AQMP was estimated at approximately \$15,000 per ton of PM₁₀, but was determined not cost-effective for reducing PM_{2.5} at over \$400,000 per ton. Adjusting previous AQMP cost assumptions to 2022 costs would result in a cost-effectiveness estimate higher than \$400,000 per ton of PM_{2.5}. Additionally, it is

⁴⁴ Wexler, A., Wallis, C. D., Chuang, P., and Leandro, M. (2023). Assessing Particulate Emissions from Power Plant Cooling Towers. <https://www.energy.ca.gov/publications/2023/assessing-particulate-emissions-power-plant-cooling-towers>

possible that the cost effectiveness may be even higher if the existing drift elimination efficiencies installed at cooling towers are greater than specified, as outlined in the CEC study.

Summary Table

Type of Analysis	Emission Reduction	Technological Feasibility	Economic Feasibility	Feasible Measure
BACM/BACT	TBD	Yes	No	No
Additional feasible measure		Yes	No	No
MSM		Yes	No	No

Other Considerations

South Coast AQMD has determined that further evaluation is required prior to implementing this control measure. Control measure BCM-13 proposes development of an emissions inventory, equipment universe, and improved emission factors for cooling towers.

Potential Control Measure 4 - Emission Reductions from Livestock Waste at Confined Animal Facilities

Target Pollutant

NH₃

Synopsis

There are two components to this control measure. The first component seeks to lower the applicability threshold in South Coast AQMD Rule 223 to align with the more stringent thresholds in SJVAPCD Rule 4570 (1,000 milk cows in South Coast AQMD vs. 500 milk cows in SJVAPCD, and 650,000 birds in South

Coast AQMD vs. 400,000 birds in SJVAPCD). The second component seeks to introduce more stringent requirements to reduce ammonia emissions at dairies and other Confined Animal Facilities (CAFs).

Given the larger presence of dairies and CAFs in SJV, South Coast AQMD consulted U.S. EPA's recent actions on SJVAPCD's 2018 PM_{2.5} SIP to develop a comprehensive list of ammonia control strategies that apply to this source category. U.S. EPA published a proposed rule on December 29, 2021 to approve SJVAPCD's 2018 Serious Area Plan for the 2012 annual PM_{2.5} NAAQS.⁴⁵ However, based on adverse public comments, U.S. EPA reversed course and proposed disapproval of several plan requirements on October 5, 2022.⁴⁶ A central issue in U.S. EPA's proposed disapproval relates to SJVAPCD's BACM analysis for Rule 4570. U.S. EPA referenced several research studies and guidance documents for ammonia reductions from CAFs that were not evaluated as part of the process to develop potential control measures. One of the referenced guidance documents was developed by U.S. EPA and the U.S. Department of Agriculture (USDA) in 2017 and is titled "*Agricultural Air Quality Conservation Measures: Reference Guide for Poultry and Livestock Production Systems*."⁴⁷ After consulting these sources, a comprehensive list of mitigation measures with the potential to reduce ammonia emissions from CAFs was developed (see Table III-9).

Brief descriptions of the measures listed in Table 4 that reduce NH₃ emissions from livestock waste are provided below. Measures previously considered as part of the 2016 AQMP are also discussed.

Dietary Manipulation/Feed Additives

Dietary formulation changes involve changes in feed ingredients or ration formulations to provide essential nutrients to meet animal requirements while minimizing excess amounts of nutrients. Dietary manipulation such as lowering the protein content and including high-fiber ingredients is a potential method to decrease ammonia emissions from monogastric animals' and ruminants' manure. However, lowering the dietary protein content of dairy cattle negatively impacts milk production according to UC Davis Extension Specialist Dr. Peter Robinson.⁴⁸

Group and Phase Feeding

Group and phase feeding practices involve separating animals by age or production state (phase), and/or by sex to provide diets that more closely match the different nutritional needs of each phase and sex to avoid providing excess nutrients in diets.

Litter Amendments and Manure Additives

⁴⁸ A list of selected scientific publications by Peter Robinson, PhD is available on the UC Davis website at: <https://animalscience.ucdavis.edu/people/faculty/peter-robinson/Articles/Scientific-Publications>

Litter amendments and manure additives address the generation of emissions by changing manure properties to prevent emissions from forming. Commonly used litter amendments and manure additive categories include: (1) chemicals (i.e., acidifiers); (2) adsorbents; and (3) biological compounds (i.e., microbes or enzymes).

Oil Spray/Sprinkling

Vegetable oil (crude canola, purified canola, flax, corn, sunflower or soybean oils) is sprayed into the air in animal production areas, and particles that stick to the droplets settle onto the building surfaces. While this practice originated as a measure to reduce PM emissions, smaller reductions of hydrogen sulfide and NH₃ emissions have also been observed with the use of oil sprinkling.

Biofilters

A biofilter is an air filtration and odor mitigation system that channels building exhaust through a mixture of organic materials (e.g., compost, wood chips) that support microbial growth. An air distribution system distributes the pollutant-laden air from the building exhaust to the biofilter bed (media) where microorganisms living on the biofilter media break down the pollutant gases into carbon dioxide (CO₂), water and salts.

Wet scrubbers

Wet scrubbers can be used to reduce emissions from mechanically ventilated animal production houses. The wet scrubbers used in animal production operations are usually custom designed and use either water droplets or chemical (e.g., acidic) droplets to capture pollutants.

Windbreaks and Shelterbreaks

Using upwind windbreaks or shelterbreaks can reduce exchange of fresh air over animal housing and manure storages, which can reduce the potential for emissions from these sources.

Manure Storage Covers

Manure is often stored prior to land application – either as a liquid or slurry in open earthen basins or tanks or as a solid in stacks or piles. Emissions are generated due to biological activity within the decomposing manure. Air exchange caused by wind passing over these storages is a source of emissions as pollutants are drawn by diffusion from areas of higher concentration (manure storages) to areas of lower concentration (fresh air). Additionally, the direct transport of pollutants from these storages by the wind is another source of emissions. The use of a cover allows producers to significantly limit the release and transport of these emissions.

Solid-Liquid Separation

The decomposition of manure solids during the anaerobic storage of liquid or slurry manures lead to increased emissions. For manure streams handled as a slurry, separation of the solid and liquid portions prior to storage, additional treatment and/or land application may reduce emissions.

Oxygenation of Liquid Manure Lagoons

Lagoons that treat and store manure as a liquid or slurry can be designed as either anaerobic or aerobic lagoons. As the manure in the lagoon decomposes anaerobically, it releases emissions. If sufficient oxygen is provided to the system, aerobic bacteria can break down these organic compounds into simpler forms.

Composting

Composting is a biological method of decomposition of manure in a controlled manner that involves maintaining specific carbon to nitrogen (C:N) ratios, moisture levels, temperature and aeration levels. Similar to the benefits of aeration for liquid or slurry manure, properly managed compost operations can reduce ammonia emissions from solid manure. Finished compost is a stable product that can serve as a valuable soil amendment.

Anaerobic Digester

Anaerobic digestion (AD) is a process in which microorganisms break down manure, but unlike composting, AD occurs in the absence of oxygen, or anaerobically. While AD occurs naturally in traditional manure storage and treatment lagoons under anaerobic conditions, it is usually incomplete and inefficient. By using a higher loading rate, incorporating mixing, heating the process and maintaining a consistent volume, anaerobic digestion will maximize reductions.

Timing of Land Application

Timing of land management practices such as application according to agronomic recommendation and application under cool and calm weather conditions can reduce emissions. Agronomic application is the application of nutrients to meet crop needs, including the timing of those nutrient needs. By matching crop needs to available nutrients, over-application of nitrogen can be reduced, which will minimize subsequent NH₃ and N₂O emissions.

Additionally, temperature, humidity, wind speed and precipitation influence the rate of NH₃, PM and odor losses. The application of manure during cool, calm weather with higher humidity will decrease the amount of NH₃ volatilized from the manure. Applying nutrients in the spring prior to planting when crops are ready to utilize the nitrogen can reduce NH₃ emissions compared to applying in the fall. Light precipitation events following application can also decrease NH₃ volatilization by binding NH₃ to soil clays.

Injection

Manure from animal production facilities is usually applied to fertilize crops on land. Liquid and/or slurry manure (e.g., manure from swine, dairy production) is injected beneath the soil surface at a minimum depth of four inches by a tractor-pulled tank wagon or dragline injection system to conserve nitrogen.

Incorporation

Incorporation involves mixing manure or litter with surface soil at a minimum depth of four inches such that at least 80 percent of applied manure is covered with soil. Broadcasting manure, either solid or liquid, without incorporation results in the highest emissions. Incorporation may be accomplished by using standard agricultural practices (e.g., tandem-disk tillage) or other equivalent practices that provide 80 percent soil coverage.

Banding

Banding of manure involves the application of liquid manure in narrow bands either directly from a spreader hose or through a sliding shoe that rides along the soil surface. Banding allows relatively low-pressure manure application with less soil disturbance than incorporation. Reduced volatilization of gases from the low pressure application results in reductions of NH₃ emissions.

Potential Emission Reduction

Table III-10
2030 Baseline Emissions from Livestock Waste

Facility type	NH ₃ Emissions (tpd)
Dairy Cattle	5.08
Range Cattle	0.13
Poultry - Layers	0.28
Swine	0.02
Sheep	0.08
Horses	0.51
Goats and Others	0.05
Total	6.13

As shown in Table III-10, the total inventory for this source category is 6.13 tpd of NH₃ in 2030, yet dairy cattle are responsible for over 80 percent of those emissions. Lowering Rule 223 applicability thresholds results in an estimated 5 percent NH₃ emission reduction (from additional 46,000 cows regulated relative to a threshold reduction from 1,000 cows to 500 and 650,000 chickens to 400,000). Thus, the estimated reduction from lowering the thresholds in Rule 223 for dairy cattle and poultry layers is 0.27 tpd.

Emission reductions are estimated for the incorporation of solid cattle manure within 24 hours and acidifying amendments for poultry litter. Assuming that 2.8 percent of dairy cattle NH₃ emissions are from solid manure land application and high-disturbance land incorporation within 24 hours reduces NH₃ emissions by 75 percent, the NH₃ reductions are estimated to be 0.11 tpd.⁴⁹ Regarding acidifying

⁴⁹ Ammonia: Supplemental Information for EPA in Support of 15 µg/m³ Annual PM_{2.5} Standard, CARB. March 2023

amendments, a recent study found that an application rate of 98 kg of aluminum sulfate per 100 square meters incorporated into poultry litter reduced overall ammonia emissions from poultry broilers by 35 percent.⁵⁰ Assuming the same control efficiency for poultry layers results in NH₃ emission reductions of 0.098 tpd.

Technological Feasibility

Lowering Rule 223 applicability thresholds is technologically feasible. The remainder of the feasibility assessment concerns the mitigation measures listed in Table III-9.

It is not feasible for all CAFs to implement the same mitigation measures due to various factors, such as infrastructure, conditional use permits, water quality regulations, production contracts, and other limitations. Furthermore, CAFs in the Basin face unique challenges including hot, dry summers, drought conditions, and strict water regulations, which render some measures infeasible. The mitigation measures included in Rule 223 provide the owners and operators of CAFs much needed flexibility to choose the mitigation measures that make the best environmental and economic sense for their facility, while maximizing the amount of emission reductions. Nonetheless, the mitigation measures listed in Table III-9 provide potential opportunities to further reduce emissions.

CARB recently conducted an exhaustive feasibility analysis of the mitigation measures listed in Table III-9.⁵¹ This feasibility analysis was relied upon as a screening tool to identify which of the mitigation measures deserve increased scrutiny in South Coast AQMD's analysis. CARB identified the following measures with theoretical potential to further reduce emissions from dairies and poultry operations:

1. Incorporation of solid cattle manure within 24 hours

Land incorporation reduces NH₃ emissions by decreasing the exposed surface area of manure. Rule 223 includes land incorporation of all manure within 72 hours of removal as a Class One Mitigation Measure. It is technologically feasible to reduce the window from 72 hours to 24 hours while allowing exceptions (e.g., for extreme weather). High-disturbance land incorporation, which requires chisel plowing followed by secondary tillage with a disk harrow or field cultivator, is expected to achieve the greatest reductions.

2. Acidifying amendments for poultry litter

Ammonia is a weak base and reducing the pH of litter binds ammonia and reduces its volatilization. Aluminum sulfate, also known as alum, is a common compound used to treat poultry litter to reduce ammonia emissions and bind phosphorous to prevent runoff. It is technologically feasible to require the application of alum to poultry litter.

⁵⁰ Anderson, K.; Moore, P.A., Jr.; Martin, J.; Ashworth, A.J. (2020) Effect of a New Manure Amendment on Ammonia Emissions from Poultry Litter. *Atmosphere*, 11, 257. <https://doi.org/10.3390/atmos11030257>

⁵¹ Ammonia: Supplemental Information for EPA in Support of 15 µg/m³ Annual PM_{2.5} Standard, CARB. March 2023

Economic Feasibility

The cost-effectiveness for high-disturbance incorporation of solid manure is estimated to range from \$26,400/ton to \$256,840/ton depending on whether only additional labor is required or a custom farm service must be used.⁵²

The application rate of alum on a per bird basis is 0.074 kg/bird⁵³ and the South Coast Air Basin NH3 emission factor for poultry layers is 0.19 lbs/head-year. Assuming a 35 percent reduction in NH3 emissions, the reduction is equivalent to 0.067 lbs/head-year. The application cost is estimated as \$0.63/head.⁵⁴ Alum must be applied prior to placing each flock and it is assumed that there is one poultry layers flock per year. Therefore, the cost-effectiveness is calculated as follows:

$$\$0.63/\text{head} \div 0.067 \text{ lbs/head-year} \times 2,000 \text{ lb/ton} = \$18,806/\text{ton}$$

Summary Table

Type of Analysis	Emission Reduction	Technological Feasibility	Economic Feasibility	Feasible Measure
BACM/BACT	0.48 tpd of NH3 by 2030	No	No	No
Additional feasible measure		No	No	No
MSM		Yes Feasible	Yes Feasible	Yes - partial

This PCM has been incorporated into the control strategy as BCM-08. For the purposes of satisfying MSM, South Coast AQMD commits to consider lowering the applicability threshold in Rule 223. As the Basin was reclassified to “serious” nonattainment effective December 2020, the deadline for implementation of BACM is December 2024. During that time, South Coast AQMD has developed multiple SIP revisions, including this PM2.5 Plan. Independent of MSM, the feasibility of the mitigation measures will be further explored during rulemaking. Considering South Coast AQMD’s robust, extensive and thorough rulemaking legally mandated public process and noticing requirements, rulemaking for this measure cannot be feasibly implemented-completed within 4 years of reclassification by December 2024, nor can it be implemented-completed by 2025, the statutory “serious” area attainment year. In addition, the time for CAFs to apply for permits and implement mitigation measures must be considered. It is unreasonable to expect that this measure could be adopted and implemented within the time constraints for BACM and additional feasible measures. However, considering the 5-year extension of the attainment year pursuant to CAA section 188(e), this measure can be feasibly implemented in whole or in part by 2030.

Independent of MSM, this measure will further assess the feasibility of the mitigation measures discussed, including acidifying amendments for poultry litter and high disturbance incorporation of cattle manure.

Potential Control Measure 5 - Further Emission Reductions from Agricultural, Prescribed, and Training Burning

Target Pollutant

PM2.5

Synopsis

This control measure would seek further emission reductions from certain categories of open burning including agricultural and prescribed (e.g., forestry service) burning activities, as well as training burns. Agricultural burning involves the collection and combustion of vegetation produced from the growing and harvesting of crops. Prescribed burning is the planned burning of vegetation, usually conducted by a fire agency or the forest service to mitigate wildfire impacts or control plant disease and pests. Training burns are conducted by fire departments to practice suppressing fires. Rule 444 includes a Basin-wide no-burn provision when forecasted AQI is expected to exceed 150 in any area of the Basin. If the Basin-maximum forecasted AQI does not exceed 150, prescribed burning is prohibited in areas with AQI values exceeding 100 but agricultural burning is still prohibited for the entire Basin. While this provision controls episodic emissions on days with the worst air quality, it does not produce emission reductions on an annual basis since burning activities are shifted to other days.

PM2.5 emission reductions from agricultural burning can be achieved through incentivizing the use of alternatives (e.g., chipping/grinding or composting), with priority for eliminating burn projects located near sensitive receptors. The alternatives will produce emissions directly (e.g., chipping and grinding) or indirectly (e.g., transport of material to composting facilities) although they are still anticipated to result in a net emission reduction.

Potential Emission Reduction

The 2030 baseline emission inventory is 0.27 tpd of PM2.5 for prescribed and training burns.

The 2030 baseline emission inventory is 0.0086 tpd of PM2.5 for agricultural burning.

Technological Feasibility

Burning alternatives such as chipping/grinding or composting are widely available for agricultural applications.

The Menu of Control Measures developed by the U.S. EPA also recommends the inclusion of a provision to require higher fuel moistures during prescribed burns. For forestry burning, this is intended to decrease emissions by decreasing the amount of fuel burned and can be accomplished by either removing lighter and drier fuels or burning in early spring when moisture levels are naturally higher. There are renewed efforts to drastically increase the number of acres treated by prescribed fire in order to reduce the air quality impacts of increasingly intense wildfires caused by years of drought due to climate change and past forest management practices that have allowed the accumulation of the understory in forests throughout the west. Forest management, whether through chipping and grinding or prescribed fire, reduces overall emissions by reducing the intensity and available fuel of wildfires occurring on recently treated lands.

The distinct wet and dry seasons in the South Coast Air Basin along with poor summertime air quality that may restrict prescribed fire for nearly half of a year in some locations make finding suitable conditions for prescribed fire extremely challenging for fire agencies. Further restricting the number of days available for prescribed fire by setting fuel moisture requirements is inconsistent with the goal of increasing the number of acres treated by prescribed fire and may result in higher intensity wildfires, increased threats to life and property, and increased emissions that occur from fires that burn on untreated lands. Similarly, restricting training burns runs counter to the goal of wildfire containment as experienced firefighting crews need to rapidly mobilize in the event of wildfires. Further restricting their ability to train will hamper those efforts. Therefore, this provision in the Menu of Control Measures is not technologically feasible for prescribed and training burns.

Economic Feasibility

The cost-effectiveness of this measure as it applies to agriculture has not been estimated. However, costs to implement burning alternatives would be expected to be higher due to equipment and labor costs. Agricultural burning is much more prevalent in the SJVAPCD (36 percent of statewide emissions compared to <1 percent in the South Coast Air Basin).⁵⁵ The extent of burning is reported to CARB on an annual basis based on the acreage of crops cleared to produce a burn pile. In 2022, there were only 10.1 acres cleared for agricultural burning in the Basin.⁵⁶ By comparison, there were 33,451 acres cleared in 2022 for agricultural burning in the SJVAPCD.⁵⁷ Due to the high incremental cost associated with chipping and grinding, SJVAPCD provides incentives ranging from \$300/acre to \$1,300/acre depending on the crop and whether soil incorporation is included.⁵⁸ The extremely limited extent of agricultural burning combined with the high cost of alternatives suggest that this measure is economically infeasible and has no practical air quality benefit. Nevertheless, South Coast AQMD commits to perform outreach to the entities that perform agricultural burns to raise awareness of alternatives such as chipping and grinding.

Summary Table

Type of Analysis	Emission Reduction	Technological Feasibility	Economic Feasibility	Feasible Measure
BACM/BACT	TBD	No	No	No
Additional feasible measure		No	No	No
MSM		No	No	No

Control measure BCM-17 involves a wildfire prevention program that seeks to incentivize hand-thinning, mechanical thinning, and chipping and grinding to mitigate excess fuels in urban-wild-interface areas of the San Bernardino National Forest. The scope of the measure is limited to a pilot project to further assess the effectiveness of incentive programs.

Potential Control Measure 6 - Further Emission Reductions from Commercial Cooking - Charbroilers

Target Pollutant

PM_{2.5}

Synopsis

Rule 1138 regulates VOC and PM emissions from restaurant operations by requiring the installation of flameless catalytic oxidizers, or equivalent control devices, to chain-driven charbroilers. The Rule covers chain-driven charbroilers cooking 875 pounds of meat or more per week, applicable mostly to large restaurant chains. Although under-fired charbroilers are another source of emissions from restaurant operations, no cost-effective control technology was identified for this type of equipment at the time of rule adoption. In the decade following adoption of Rule 1138, staff reported to the Governing Board regarding under-fired charbroiler control technology assessments, but amending the rule was determined to be infeasible. In 2008, staff reinitiated rule development for charbroilers and held a series of working group meetings and a public workshop. Rule amendment was again concluded to be infeasible due to the lack of affordable control technologies.

Staff has conducted an analysis of the state of PM control technology as well as potentially more stringent requirements in some of the other air districts. SJVAPCD Rule 4692 reduces PM emissions by requiring catalytic oxidizers for chain-driven charbroilers cooking 400 pounds of meat or more per week. This threshold is more stringent than that in Rule 1138 which applies to chain-driven charbroilers cooking 875 pounds of meat or more per week. Staff commits to evaluate the feasibility of lowering the applicability threshold for chain-driven charbroilers in Rule 1138.

Finally, SJVAPCD amended Rule 4692 to require registration and reporting for under-fired charbroilers. SJVAPCD Rule 4692 requires a one-time report for all commercial under-fired charbroilers submitted. Information required include typical details (name, location of establishment), number and size of cooking surface of all underfired charbroilers, type of fuel, type and pounds of meat cooked on a weekly basis, operating hours of cooking operation, flow rate (in cubic feet per minute, or CFM) of hood or exhaust system, manufacturer, and model of any installed pollution control devices (particulates, kitchen smoke, and/or odors). See below for the information that must be provided:⁵⁹

- Name and location of the commercial cooking operation;
- Number and size, in cooking surface square feet, of all underfired charbroilers at the commercial cooking operation;
- Type of fuel used to heat the underfired charbroiler(s);
- Type and quantity, in pounds, of meat cooked on the underfired charbroiler(s) on a weekly basis for the previous 12-month period;
- Daily operating hours of the commercial cooking operation;
- Flowrate (cubic feet per minute) of hood or exhaust system(s) serving each underfired charbroiler; and
- The manufacturer and model of any installed pollution control devices designed for the reduction of particulates, kitchen smoke and/or odor.

South Coast AQMD Rule 222 also requires that all charbroilers in the South Coast jurisdiction be registered and provide sufficient data as determined by South Coast AQMD to determine compliance. Registrations must be renewed annually and refiled if there is a change of ownership/name/location.

Staff does not interpret registration and reporting requirements as an applicable MSM. This is because these requirements are purely administrative and do not achieve emission reductions. Nevertheless, staff commits to consider a registration program to improve the accuracy of the emissions inventory for charbroilers.

Potential Emission Reduction

The 2030 baseline inventory is 9.13 tpd of PM2.5 for this source category.

Potential emission reductions for lowering the rule applicability threshold for chain-driven charbroilers cannot be determined due to a lack of updated data with meat cooked throughput.

Technological Feasibility

It is technologically feasible to lower the rule applicability threshold for chain-driven charbroilers.

⁵⁹ SJVAPCD Rule 4692 Commercial Charbroiling (Adopted March 21, 2002; Amended September 17, 2009; Amended June 21, 2018)

Economic Feasibility

While the number of chain-driven charbroilers that would be affected by lowering the threshold is unknown, SJVAPCD Rule 4692 already enforces the lower threshold so it is reasonable to conclude that this control measure is economically feasible.

Summary Table

Type of Analysis	Emission Reduction	Technological Feasibility	Economic Feasibility	Feasible Measure
BACM/BACT	TBD	No	No	No
Additional feasible measure		No	No	No
MSM		Yes	Yes	Yes

This PCM has been incorporated into the control strategy as BCM-12. As the Basin was reclassified to “serious” nonattainment effective December 2020, the deadline for implementation of BACM is December 2024. During that time, South Coast AQMD has developed multiple SIP revisions, including this PM2.5 Plan. Considering South Coast AQMD’s robust, legally mandated public process and noticing requirements, rulemaking for this measure cannot be feasibly completed by December 2024, nor can it be completed by 2025, the statutory “serious” area attainment year. In addition, the time for affected restaurants to install and operate catalytic oxidizers must be considered. It is unreasonable to expect that this measure could be adopted and implemented within the time constraints for BACM and additional feasible measures. However, considering the 5-year extension of the attainment year pursuant to CAA section 188(e), this measure can be feasibly implemented in whole or in part by 2030. Considering South Coast AQMD’s extensive and thorough rulemaking public process, BCM-12 cannot be feasibly implemented within 4 years of reclassification, nor can it be implemented by 2025, the statutory “serious” area attainment year. However, considering the 5 year extension of the attainment year pursuant to CAA section 188(e), BCM-12 can be feasibly implemented in whole or in part by 2030.

Potential Control Measure 7 - Further Emission Reductions from Paved Road Dust

Target Pollutant

PM2.5

Synopsis

This measure would seek further PM2.5 emission reductions from fugitive dust sources, primarily paved roads. While fugitive dust emissions from agriculture and construction are primarily in the coarse size fraction (PM10-2.5), entrained paved road dust is a major direct PM2.5 source due to the large number of roadways and high traffic volumes in the region. South Coast AQMD Rule 1186 - PM10 Emissions from

Paved and Unpaved Roads, and Livestock Operations establishes requirements to prevent material from being deposited on roadways and requires local jurisdictions to procure certified street sweeping equipment.⁶⁰

Most cities in the Basin have routine street sweeping frequencies of once or twice per week due to stormwater regulations. Specifically, existing National Pollution Discharge Elimination System (NPDES) permits required under the Clean Water Act currently specify street sweeping frequencies as part of a comprehensive program to reduce debris from entering storm drains.⁶¹ Thus, regulations are currently in place to require street sweeping at specified frequencies with South Coast AQMD-certified equipment. Accordingly, the BACM analysis included in the 2016 AQMP concluded the South Coast AQMD's existing rules and regulations are equivalent to, or more stringent than other districts' rules and regulations and met the BACM requirements. The 2016 AQMP did, however, include Control Measure BCM-03 (Further Emission Reductions from Paved Road Dust Sources) that proposed a review of current South Coast AQMD Rule requirements to determine if additional emission reductions could be achieved. Therefore, this PM2.5 Plan includes control measure BCM-14 that proposes an additional evaluation of paved road dust emissions.

Potential controls may include establishing increased sweeping frequencies for freeways and highways, establishing new test protocols to measure both PM2.5 and PM10 road dust emissions from sweepers, and requiring use of the most efficient sweepers with the lowest dust entrainment rates.

Potential Emission Reduction

The 2030 baseline inventory is 9.11 tpd of PM2.5 for this source category.
Potential emission reduction from this control measure is TBD.

Technological Feasibility

Studies that examine the effect of street sweeping on PM levels are scarce. A recent study in Chiayi City, Taiwan concluded that street sweeping combined with street washing is effective at reducing ultrafine particle concentrations.⁶² Another study conducted in Krakow, Poland found that street sweeping followed by intensive washing reduced road dust PM2.5 by 20-33 percent.⁶³ However, due to the tendency for the South Coast Air Basin to experience extreme drought, street washing is infeasible. Additionally, NPDES regulations prohibit street washing. Thus, these studies are not applicable to our region. The only studies identified as potentially applicable to our region found that closed system

⁶⁰ <http://www.aqmd.gov/docs/default-source/rule-book/support-documents/rule-1186/certified-street-sweepers-equipment-list.pdf?sfvrsn=2>

⁶¹ City of Fullerton, 2015. Contact with Ty Richter, Street Supervisor, City of Fullerton, September 2015.

⁶² Do the Street Sweeping and Washing Work for Reducing the Near-ground Levels of Fine Particulate Matter and Related Pollutants? <https://doi.org/10.4209/aagr.220338>

⁶³ Impact of Street Sweeping and Washing on the PM10 and PM2.5 Concentrations in Cracow (Poland) <https://ros.edu.pl/index.php?view=article&id=740:043-ros-v21-r2019&catid=51&lang=pl>

regenerative air sweepers are more efficient and less polluting compared to vacuum and mechanical brush sweepers.^{64,65}

Mandating increased street sweeping frequencies has unknown impacts on PM_{2.5} levels. Therefore, a pilot project along with a comprehensive atmospheric measurement campaign would be needed to assess the effectiveness of street sweeping frequency and technology as a method to reduce ambient PM_{2.5}. New test protocols that evaluate the PM_{2.5} performance of sweepers, such as those in Toronto and Europe,^{66,67} may be needed as well.

Economic Feasibility

Street sweeping costs vary greatly based on the number of miles and frequencies and whether the work is conducted with in-house or contracted resources. A survey of several large cities conducted in 2018 determined that the median annual cost of street sweeping was \$52.31 per curb mile.⁶⁸ The cost of mandating increased street sweeping frequencies can be substantial considering that the City of Los Angeles alone has over 230,000 curb miles to maintain. A pilot project would provide further insight into the cost-effectiveness of this measure.

Summary Table

Type of Analysis	Emission Reduction	Technological Feasibility	Economic Feasibility	Feasible Measure
BACM/BACT	TBD	No	No	No
Additional feasible measure		No	No	No
MSM		Yes	No	No

Other Considerations

South Coast AQMD has determined that further evaluation is required prior to fully implementing this control measure. Control measure BCM-14 proposes a pilot project to assess the effectiveness of increased street sweeping using regenerative air sweepers.

Potential Control Measure 8 - Further Emission Reductions from Wood-Burning Fireplaces and Wood Stoves

Target Pollutant

PM2.5

Synopsis

Rule 445 currently implements robust controls designed to reduce PM2.5 emissions from wood-burning devices. During wood-burning season, PM2.5 mandatory burning curtailment (No-Burn days) may be declared by the Executive Officer based on PM2.5 air quality forecast. However, there is an exemption for low-income households defined as “any household that receives financial assistance through reduced electric or gas bills from an electric or natural gas utility based on household income levels.” There are two financial assistance programs in California: Family Electric Rate Assistance (FERA) and California Alternate Rates for Energy (CARE). Staff estimated that 15-20 percent of single-family households qualify for CARE over an inland range covering Los Angeles and Orange Counties.⁶⁹ This is potentially a lower bound estimate of the households qualifying for the low-income exemption in Rule 445 since the qualified income thresholds are slightly higher for FERA than CARE. In addition, this PCM evaluates the feasibility of the proposed curtailment threshold of 25 µg/m3.

Potential Emission Reduction

The 2030 baseline inventory is 4.82 tpd of PM2.5 for all wood-burning devices.

~~Potential emission reductions have not been estimated.~~

Technological Feasibility

It is technologically feasible to lower the curtailment threshold and remove the low-income exemption for households with an alternative source of heat.

Economic Feasibility

Removing the low-income exemption from the mandatory curtailment would result in indeterminate cost increases to the impacted community. However, this control measure does not propose to modify existing curtailment exemptions provided to sole source of heat households or those not serviced by natural gas.

⁶⁹ Net Emissions Analysis Tool (NEAT) documentation. <http://www.aqmd.gov/home/air-quality/clean-air-plans/air-quality-mgt-plan/neat-main>

~~This potential control measure would~~ Removal of the low-income exemption and the lower curtailment threshold would not affect economic feasibility since season woods cost higher than natural gas in The Basin and majority of wood burning are ~~effectively only apply to~~ ambiance burning in low income households. Therefore, it is economically feasible.

Summary Table

Type of Analysis	Emission Reduction	Technological Feasibility	Economic Feasibility	Feasible Measure
BACM/BACT	0.33 tpd PM2.5TBD	No	No	No
Additional feasible measure		No	No	No
MSM		Feasible Yes	Feasible Yes	Yes

This PCM has been incorporated into the control strategy as BCM-18. As the Basin was reclassified to “serious” nonattainment effective December 2020, the deadline for implementation of BACM is December 2024. During that time, South Coast AQMD has developed multiple SIP revisions, including this PM2.5 Plan. Considering South Coast AQMD’s robust, legally mandated public process and noticing requirements, rulemaking for this measure cannot be feasibly completed by December 2024, nor can it be completed by 2025, the statutory “serious” area attainment year. In addition, the “serious” area plan submitted to the U.S. EPA in 2017 demonstrated Rule 445 satisfying BACM requirements at the time of the submittal. Due to unforeseen circumstances, the plan was withdrawn effective in June 2023 and a new BACM demonstration in conjunction with a new attainment strategy was developed. Given the short timeline from the new BACM demonstration to the statutory BACM implementation timeline, December 2024, it is not feasible to implement this measure as BACM. However, considering the 5 year extension of the attainment year pursuant to CAA section 188(e), this measure can be feasibly implemented in whole or in part by 2030. Considering South Coast AQMD’s extensive and thorough rulemaking public process, this measure cannot be feasibly implemented within 4 years of reclassification, nor can it be implemented by 2025, the statutory “serious” area attainment year. However, considering the 5-year extension of the attainment year pursuant to CAA section 188(e), this measure can be feasibly implemented by 2030.

Potential Control Measure 9 - Emission Reductions from Organic Waste Composting

Target Pollutant

NH3

Synopsis

This proposed control measure would seek emission reductions of NH3 from composting of organic waste (i.e., greenwaste, foodwaste, and agricultural waste streams). Control approaches include pollution

prevention technology, anaerobic digestion in lieu of composting, and restrictions for direct application of uncomposted, chipped or ground greenwaste (e.g., compostable mulch) to public lands.

California has passed legislation to divert organic waste from landfills including AB 1826 (Mandatory Commercial Organics Recycling; Chesbro, Chapter 727, Statutes of 2014) and SB 1383 (Short-Lived Climate Pollutants; Lara, Chapter 395, Statutes of 2016). SB 1383 sets statewide targets to reduce disposal of organic waste in landfills by 75 percent from 2014 levels and to save at least 20 percent of currently disposed surplus food for consumption by 2025.⁷⁰ SB 1383 organic waste mandates are implemented by local jurisdictions with oversight from California's Department of Resources Recycling and Recovery (CalRecycle). CalRecycle conducted a formal rulemaking process through collaboration with other stakeholders that resulted in regulations for organic waste management programs. Organic waste includes a broad range of waste categories such as food, green material, landscape and pruning waste, organic textiles and carpets, lumber, wood, paper products, printing and writing paper, manure, biosolids, digestate, and sludges that will be diverted from landfills and taken to the appropriate organic waste recovery facilities. Local jurisdictions must have their organic waste management programs in effect by January 1, 2022 and are required to take enforcement against noncompliance starting January 1, 2024.⁷¹

According to Table 2-3 of CalRecycle's Final Environmental Impact Report, 46 new or expanded compost facilities and 24 new or expanded anaerobic digester facilities would be required in the South Coast Air Basin by 2030 to process the diverted waste.⁷² While overall Short-Lived Climate Pollutant emissions are expected to decline, emissions from processing of organic waste via composting and anaerobic digestion are expected to grow. Organic waste may contain pathogen infections and is known to increase NH₃ emissions, if not composted properly. Therefore, this control measure proposes minimum composting standards to eliminate pathogens and minimize NH₃ emissions. It also seeks to evaluate emerging technologies to further control emissions from organic waste.

Potential Emission Reduction

The 2030 baseline inventory is 0.67 tpd of NH₃ for this source category. Emission reductions were not estimated.

Technological Feasibility

Pollution Prevention Technology

Rule 1133.3 requires 80 percent control of VOC and NH₃ emissions for a greenwaste composting pile containing greater than 10 percent foodwaste. Emerging pollution prevention technologies are able to process these waste materials without the microbial decomposition of organic materials, concurrently

⁷⁰ <https://calrecycle.ca.gov/organics/slcp/>

⁷¹ An Overview of SB 1383's Organic Waste Reduction Requirements.
<https://www2.calrecycle.ca.gov/Docs/Web/115800>

⁷² CalRecycle Final Environmental Impact Report. <https://www2.calrecycle.ca.gov/Docs/Web/119973>

killing pathogens and thereby minimizing VOC and NH₃ generation from the process. As an example, ~~ReGreen~~ Regreen International Solutions Technology, Inc. (ReGreenRegreen) systems can handle and process organic material and municipal solid waste into a stable byproduct such as animal feed, soil amendments/fertilizers, or clean-burning energy pellets. ~~Another example is Waste Management (WM's) proprietary Centralized Organic Recycling equipment (CORG) process that recycles commercial and institutional pre- and post-consumer food waste into an Engineered BioSlurry (EBS) that is added to wastewater treatment plant anaerobic digesters to increase the production of biogas.~~

Anaerobic Digestion

Anaerobic digestion is a process through which bacteria digest organic matter such as animal manure, wastewater biosolids (e.g., municipal sewage sludge), and food waste in the absence of oxygen. Anaerobic digestion for biogas takes place in a sealed vessel called a reactor, which is designed and constructed in various shapes and sizes specific to the site and feedstock conditions. These reactors contain complex microbial communities that digest the waste and produce resultant biogas and other useful coproducts (i.e., solid and liquid portions of the digestate). There are two types of anaerobic digester (AD) systems. Dry AD has a higher content of total solids greater than 15 percent and is best if feedstock is rich in green waste (up to 50 percent green waste). Wet AD has a lower content of total solids less than 15 percent and is best if the feedstock has no green waste. Dry AD generally requires larger and adjacent composting area, providing lower biogas yield and producing more solid digestate than in the wet AD system. Co-digestion is a wet AD system in which multiple organic materials can be combined digested in one digester. Co-digested materials include manure, food waste (pre- and post-consumer), crop residues, and fats, oils and greases (FOG) from restaurant grease traps, and many other sources. Co-digestion can increase biogas production from low-yielding or difficult-to-digest organic waste. There is one co-digestion facility operating in Los Angeles County that receives food waste and sewage sludge to produce biogas for Compressed Natural Gas (CNG) transportation fuel and electricity.⁷³ This co-digestion facility uses Waste Management (WM's) proprietary Centralized Organic Recycling equipment (CORG) process that recycles commercial and institutional pre- and post-consumer food waste into an Engineered BioSlurry (EBS) that is added to wastewater treatment plant ADs to increase the production of biogas. There are also four standalone anaerobic digestion facilities operating in the South Coast AQMD jurisdiction, which accept and process food waste and other organic wastes.⁷⁴

Composting of Chipped Green Waste Used for Land Application

Shredded curbside and non-curbside green waste, if not composted properly, may increase NH₃ and VOC emissions or pathogen infections when used as ground cover. Emissions can be reduced by having those materials go through the active phase of composting for at least 15 days. Approximately 85 percent of NH₃ emissions occur during the first 15 days of the 22-day active phase composting period required by

⁷³ <https://www.lacsd.org/services/solid-waste-programs/food-waste-recycling>

⁷⁴ <https://www2.calrecycle.ca.gov/Docs/Web/115971>. Updated March 2023

Rule 1133.3.^{75,76} In addition, California Code of Regulations, Title 14, Section 17868.3 requires a pathogen reduction period of 15 days for a windrow composting process. Therefore, NH₃ emissions can be reduced from shredded green material applied to public lands (e.g., for erosion control) by imposing restrictions such that chipped and ground greenwaste undergoes a minimum of 15 days of active phase composting before land application. Staff previously estimated NH₃ emissions from curbside greenwaste composting feedstock piles at 0.017 lbs/wet ton-day. However, emissions from a layer of land-applied shredded greenwaste materials have not been investigated and thus warrant further research. Emission reductions are estimated to be 0.08 tpd (see BCM-10 for details).

Economic Feasibility

Only the “Composting of Chipped Greenwaste Used for Land Application” ~~The portion of this potential control measure seeking reductions of uncomposted chipped and ground greenwaste~~ is considered economically feasible and has an estimated cost-effectiveness of \$91,200 per ton of NH₃ reduced (in 2022 dollars; refer to BCM-10 in Appendix IV-A). For the other portions of this potential control measure, “Pollution Prevention Technology” and “Anaerobic Digestion,” there is a lack of sufficient data on capital costs and emission controls to determine cost-effectiveness. Thus, staff estimated cost-effectiveness based upon available cost data and conservative assumptions as follows.

Pollution Prevention Technology

Estimated equipment costs for pollution prevention technology (e.g., ~~ReGreen~~ Regreen Technology) are expected to range between \$300,000 and \$400,000 for a unit that supports up to 0.5 tons/hour of feed. For full scale applications, a 5 tons/hour unit costs up to \$3.6 million (for capital costs only; operational costs are not included). Sufficient data is not available on how much emission reductions can be achieved from such a pollution prevention technology. Assuming a 5 tons/hour unit operates for 8 hours a day and 250 workdays a year, this unit can process 10,000 tons of mulch per year for a unit cost of \$360 per ton of mulch processed. Assuming this technology can entirely replace the composting operation and achieve NH₃ emission reductions at a rate of 80 percent control efficiency from the full phases of composting, the emission reductions would be 0.54 tons and cost-effectiveness is would be \$1.9 million per ton of NH₃ reduced (in 2022 dollars). The high capital cost is an impediment for widespread adoption and therefore the portion of this potential control measure related to pollution prevention technology is economically infeasible.

Anaerobic Digestion

As described in the previous section, there are anaerobic digestion plants operating in the Basin. However, sufficient data is not available on the costs and how much emission reductions can be achieved from such an anaerobic digestion or co-digestion. The cost of building a biogas facility can vary widely depending on

⁷⁵ Card, T.R. and C.E. Schmidt, 2006. Air emissions source test: Jepson Prairie Organics Compost Facility, Vacaville, CA. Report to NorCal Waste Systems, Inc.

⁷⁶ Card, T.R. and C.E. Schmidt, 2009. Northern Recycling Zamora Compost Facility Air Emissions Source Test. Report to Yolo Solano AQMD

a number of factors, including the size of the facility, the type of feedstock used, and the location of the facility to list a few, and is in general estimated to be \$400 (a simple farm installation) to \$1,500 (a municipal unit with waste sorting and biogas purification systems) per wet ton of material processed (capital costs only; operational costs are not included).⁷⁷ Greenwaste is typically not considered suitable for co-digestion because it is difficult to digest and yields low production of biogas. However, for the sake of this cost-effectiveness analysis, it was assumed very conservatively that chipped and ground mulch is a sole feedstock to co-digestion that achieves 80 percent of NH₃ emission control efficiency from anaerobic digestion that replaces the full phases of composting. The averaged control cost per ton of mulch processed is \$950 (as an average of the above cost range). This is about 2.6 times higher than the per ton cost (\$360) of a pollution prevention technology and the cost-effectiveness is \$5.0 million per ton of NH₃ reduced (in 2022 dollars). The high cost-effectiveness is an impediment for widespread adoption of this technology and therefore the anaerobic digestion portion of this potential control measure is economically infeasible.

Summary Table

Type of Analysis	Emission Reduction	Technological Feasibility	Economic Feasibility	Feasible Measure
BACM/BACT	0.08 tpd NH ₃ TPD	No	No	No
Additional feasible measure		No	No	No
MSM		Yes/Feasible	Yes/Feasible	Yes - partial

The “Composting of Chipped Greenwaste Used for Land Application” portion of this potential control measure that is considered MSM has been incorporated into control measure BCM-10. As the Basin was reclassified to “serious” nonattainment effective December 2020, the deadline for implementation of BACM is December 2024. During that time, South Coast AQMD has developed multiple SIP revisions, including this PM_{2.5} Plan. Considering South Coast AQMD’s robust, legally mandated public process and noticing requirements, rulemaking for this measure cannot be feasibly completed by December 2024, nor can it be completed by 2025, the statutory “serious” area attainment year. In addition, the time for composting facilities to expand their capacity to accommodate increased amounts of greenwaste must be considered. It is unreasonable to expect that this measure could be adopted and implemented within the time constraints for BACM and additional feasible measures. However, considering the 5-year extension of the attainment year pursuant to CAA section 188(e), this measure can be feasibly implemented in whole or in part by 2030. Considering South Coast AQMD’s extensive and thorough rulemaking public process, BCM-10 cannot be feasibly implemented within 4 years of reclassification by December 31, 2024, the deadline for implementation of BACM, nor can it be implemented by 2025, the statutory “serious” attainment year. However, considering the 5 year extension of the attainment year pursuant to CAA section 188(e), BCM-10 can be feasibly implemented in whole or in part by 2030.

Potential Control Measure 10 - Emission Reduction of PM from Asphalt Manufacturing

Target Pollutant

PM_{2.5}

Synopsis

This measure is derived from the 2012 version of U.S. EPA's Menu of Control Measures.⁷⁸ It estimates a control efficiency of 99 percent in an asphalt manufacturing facility equipped with a fabric filter, or baghouse placed in parallel inside of an enclosure. Rule 1157 - PM₁₀ Emission Reductions from Aggregate and Related Operations targets all aggregate and related operations, but does not require enclosure for all transfer points and activities. However, Rule 1155 regulates all baghouses (including those at asphalt manufacturing facilities), except for those with a filter area less than 100 ft² and requires no visible emissions at any time except for start-up and shutdown.

Potential Emission Reduction

The 2030 baseline inventory is ~~0-180.008~~ tpd of PM_{2.5} for this source category. Emission reductions have not been estimated at the transfer points and will need to be evaluated further.

Technological Feasibility

Enclosures and baghouses are generally technologically feasible. The standard (0.01 gr/dscf) for baghouses in asphalt manufacturing facilities was set forth in Rule 1155 and was fully implemented in 2013. Materials collected in a permitted PM control device must be discharged for disposal or brought back to the process through a controlled material transfer system to prevent fugitive emissions during material transfer. Such methods include, but are not limited to, shrouding or use of dust suppressant to stabilize the material. The purpose of this requirement is to control discharge of baghouse dust and prevent unwanted fugitive emissions during material transfer. Since most baghouse dusts are brought back to the process, a controlled material transfer system will help prevent fugitive emissions during material transfer.

⁷⁸ <https://www3.epa.gov/ttn/naaqs/pdfs/MenuOfControlMeasures.pdf>

Economic Feasibility

Asphalt manufacturing in the South Coast AQMD is currently regulated under Rule 1157 and Rule 1155, which require the use of filters. Baghouses are not considered economically feasible at the transfer points and activities not covered by Rule 1157 and Rule 1155. The potential emission reductions at the transfer points need to be further evaluated in order to estimate the economic feasibility or cost-effectiveness, as no data has been collected to understand the emissions at these points. However, given the emissions subject to this source category is very small, the emission reduction potential is anticipated to be de minimis, which will likely put cost effectiveness values to be very high and make this measure economically infeasible. based on the low emission inventory and the relative costs for replacement at \$27,000 per bag every three to five years.

Summary Table

Type of Analysis	Emission Reduction	Technological Feasibility	Economic Feasibility	Feasible Measure
BACM/BACT	<u>< 0.008 tpd PM_{2.5}</u>	<u>Yes</u> Feasible	Not Feasible <u>To Be Determined</u>	No
Additional feasible measure		<u>Yes</u> Feasible	Not Feasible <u>To Be Determined</u>	No
MSM		<u>Yes</u> Feasible	<u>To Be Determined</u> Not Feasible	No

Potential Control Measure 11 - Emission Reduction of PM from Wood Pulp and Paper

Target Pollutant

PM_{2.5}

Synopsis

This measure is derived from the 2012 version of U.S. EPA's Menu of Control Measures,⁷⁹ which estimated a control efficiency of 95 percent in wood pulp and paper facilities equipped with dry/wet electrostatic precipitators (ESP). Currently, there are five permitted paper and paperboard manufacturing facilities in

⁷⁹ <https://www3.epa.gov/ttn/naaqs/pdfs/MenuOfControlMeasures.pdf>

South Coast AQMD, although all rely on recycled materials. There is no source-specific control measure targeting this source category.

Potential Emission Reduction

The 2030 baseline inventory is 0.039 tpd of PM_{2.5} for this source category.

Potential emission reduction is not determined. Emission reduction techniques would need to be considered on a site-specific basis.

Technological Feasibility

An ESP is predominantly used to control PM emissions from kraft recovery furnaces used at paper manufacturing facilities that process virgin raw materials. However, manufacturing facilities in South Coast AQMD only process recycled paper and paperboard. For the recycled manufacturing facilities, very little PM is emitted from the pulp dryer, and control techniques for the paper machine vents are considered impractical because of the high moisture content, high volume of the vent exhaust gases, and the minimal pollutant concentrations.⁸⁰ As such, ESP control on PM is not technologically feasible for the recycled paper and paperboard manufacturing facilities located within South Coast AQMD.

Economic Feasibility

The control equipment for PM emissions is not expected to be cost-effective for recycled paper and paperboard manufacturing because of very high air flow from the exhaust vents on the roof top of a building where paper machine is situated, and low emission reduction potential.

Summary Table

Type of Analysis	Emission Reduction	Technological Feasibility	Economic Feasibility	Feasible Measure
BACM/BACT	N/A	No	No	No
Additional feasible measure		No	No	No
MSM		No	No	No

Staff is not aware of this control measure having been implemented in another nonattainment area or having been achieved in practice in another state for recycled paper manufacturing facilities. This PCM therefore does not meet U.S. EPA's definition of MSM.

⁸⁰ A&WMA, 2000. Air Pollution Engineering Manual, Second Edition, Air & Waste Management Association, page 804

Potential Control Measure 12 - Emission Reduction of NO_x through Reformulation and Process Modification for Cutback Asphalt

Target Pollutant

NO_x

Synopsis

This measure is derived from the 2012 version of U.S. EPA's Menu of Control Measures,⁸¹ which estimated a control efficiency of 100 percent based on the use of reformulated products and the modification of processes associated with cutback asphalt manufacturing to reduce fugitive VOC emissions. In addition, the proposed process would reduce natural gas use by an estimated 20 to 25 percent from reduced processing and transportation temperatures. The reduction in natural gas use results in NO_x emission reductions. Cutback asphalt is regulated under Rule 1108 which requires that cutback asphalt contains ≤ 0.5 percent by volume organic compounds at 260°C or lower.

Potential Emission Reduction

Emissions and emission reductions are TBD.

Technological Feasibility

Recent studies on warm-mix asphalt (WMA) have shown reductions in smoke and odors, lower emissions, improved workability, better working conditions and better performance.⁸² The study findings recommend that use of WMA be encouraged and that water-based WMA technologies should be closely monitored in mix-design and quality control/quality assurance testing to avoid moisture related issues. While WMA use may result in little or no reductions in VOC emissions, the reduced temperatures associated with WMA (approximately 20 percent lower than traditional hot-mix asphalt (HMA)) has been shown to result in a 20 to 25 percent reduction in energy usage.⁸³ WMA use is increasing throughout California, the U.S., and Europe. A survey by the National Asphalt Pavement Association found that nearly

⁸¹ <https://www3.epa.gov/ttn/naaqs/pdfs/MenuOfControlMeasures.pdf>

⁸² D. Jones, F. Farshidi, J. Harvey; Warm-Mix Asphalt Study: Summary Report on Rubberized Warm-Mix Asphalt Research (Summary Report UCPRC-SR02013-03), March 2014

⁸³ South Coast AQMD, Technology Assessment – Rule 1108 Cutback Asphalt, June 2008

one third of all asphalt pavement mix production in the U.S. is WMA, an increase of 577 percent since 2009.⁸⁴

Economic Feasibility

The cost of plant modifications to produce WMA range from \$30,000 to \$50,000. Additionally, the chemistry used to bind the aggregate is approximately \$3 to \$5 per ton more expensive than HMA. However, many facilities realize a cost savings from the process because of reduced fuel and labor costs. The WMA makes compaction easier, and the lower temperatures result in reduced transportation costs. Additionally, facilities realize a cost savings from higher reclaimed asphalt pavement content. Overall, there is no expected cost increase.

Summary Table

Type of Analysis	Emission Reduction	Technological Feasibility	Economic Feasibility	Feasible Measure*
BACM/BACT	TBD	<u>Yes</u> Feasible	<u>Yes</u> Feasible	No
Additional feasible measure		<u>Yes</u> Feasible	<u>Yes</u> Feasible	No
MSM		<u>Yes</u> Feasible	<u>Yes</u> Feasible	No

* While this measure is technologically and economically feasible in practice it is currently infeasible due to other considerations.

Other Considerations

In a white paper developed by the South Coast AQMD in 2008, staff concluded that lower-energy warm mix asphalt technologies were promising in reducing energy use and reducing NOx and VOC emissions. Nonetheless, the impact of mix and structural design, material processing requirements, construction procedures, and quality control specifications were not yet fully evaluated. In the last few years, WMA has been increasingly popular in the United States. Caltrans promotes the use of WMA because of its many improvements over HMA. In its April 2013 publication, Caltrans reported a 30 percent potential fuel savings and an 18 percent reduction in the overall GHG emissions associated with WMA.⁸⁵ The University of California Pavement Research Center (UCPRC) investigated the performance of rubberized WMA and found that in a controlled environment, rubberized WMA have better workability, and could result in potential energy savings and safer working conditions compared to HMA.⁸⁶ WMA suppliers reported 19–50 percent VOCs reduction and 60–70 percent NOx reduction in plant emissions in Europe, although

⁸⁶ Jones, D., Wu, R., Barros, C. and Peterson, J. Research Findings on the Use of Warm-Mix. February 213. http://rafoundation.org/wp-content/uploads/2013/02/040-PAP_060.pdf

increased emissions of VOCs and CO were observed in the United States.⁸⁷ Although the overall performance of WMA seemed promising, mixed results were revealed on the potential emission reductions in a field test. UCPRC measured VOCs and semi-volatile organic compounds (SVOCs) emissions from WMA and HMA at the pavement surface during construction. Results showed that depending on the mix type and the temperature inside the chamber, total reactive organic gases (ROG) emission flux of WMA could be higher or lower than HMA.¹¹ Based on current information, the emission reduction of WMA technology is still uncertain and the potential increase in VOC emissions needs to be further investigated. Although VOCs are not a significant PM_{2.5} precursor in the South Coast Air Basin, the Basin is in “extreme” nonattainment of multiple ozone NAAQS and potential increases in VOC emissions must be carefully evaluated. Therefore, staff suggests further evaluation of the emission reduction and cost-effectiveness for WMA technology prior to being considered as BACM/MSM.

Potential Control Measure 13 - Paving Unpaved Lots, Roads, and Shoulders

Target Pollutant

PM_{2.5}

Synopsis

This measure will examine the feasibility of reducing PM_{2.5} emissions from well-traveled or highly used unpaved lots, roads, and other surfaces by applying paving materials. Although the South Coast Air Basin is a highly urbanized environment, there are areas with unpaved surfaces that are used by vehicles, equipment and/or other activities that generate airborne particulate matter emissions, including PM_{2.5}. In total, there are approximately 1,900 miles of unpaved roads in the Basin. However, not all of these roads are well-traveled or highly used. The focus of this measure would be to reduce dust and PM_{2.5} emissions from unpaved surfaces located in high traffic areas that are produced by moderate to high vehicle and/or machinery activity. This includes, but is not limited to, unpaved parking lots near warehouses as well as unpaved areas used by mobile homes or other vehicles/equipment on a frequent basis. This measure does not include paving in natural or protected lands. The following sites with unpaved surfaces may be considered: roads, traffic areas, parking lots, staging or assembly areas, mobile home parks, equipment storage lots, runways, loading and unloading areas, and/or roads and other areas on agricultural lands. The following activities are not considered by this proposed control measure: routine maintenance and rehabilitation projects, and/or paving activities that are part of new development projects.

⁸⁷ U.S. Department of Transportation, Washington, DC, USA. Warm-Mix Asphalt: European Practice; International Technology Scanning Program, FHWA-PL-08-007. February 2008

Unlike SJVAPCD Rule 8061, South Coast AQMD's rules do not currently prohibit the construction of new unpaved roads in urban areas. Therefore, this measure will also examine the feasibility incorporating this prohibition into South Coast AQMD rule requirements.

Potential Emission Reduction

The 2030 baseline inventory is 1.67 tpd of PM_{2.5} for this source category.

Estimated emission reductions are TBD.

Technological Feasibility

Roadway paving is a common activity and occurs regularly throughout the Basin in construction projects and other community improvement initiatives. Other air districts have implemented unpaved road dust control measures that include paving as one method of controlling particulate matter emissions. Some have established traffic thresholds that would trigger the paving requirements set therein, and methodologies for PM emissions quantification.^{88,89} The South Coast AQMD has recently developed a Paving Project Plan for the Eastern Coachella Valley as part of the AB 617 Community Air Protection Program (CAPP), which has been approved by CARB. This plan was developed in response to community concerns related to particulate matter emissions from unpaved surfaces in the community of Eastern Coachella Valley. This paving plan includes an emissions reduction quantification methodology based on Vehicle Miles Traveled (VMT).⁹⁰ The quantification methodology has been approved by CARB and can be applied to this PCM for paving of unpaved surfaces in the Basin.

This PCM focuses on unpaved surfaces that are adjacent to high-traffic areas or highly used by vehicles and equipment causing the production of airborne particulate matter emissions, including PM_{2.5}. An additional quantification methodology may be necessary to estimate the emissions reduced by paving surfaces based on square footage or similar measure within unpaved lots that are not open to through traffic, such as warehousing operations. The amount and locations of unpaved surfaces that would benefit from this PCM are currently unknown, however South Coast AQMD is aware of several locations that could benefit from this PCM based on high truck traffic areas, goods movement corridors, warehouse locations, as well as through concerns raised by the AB 617 communities and information provided by various other sources. For example, the AB 617 community of San Bernardino/Muscoy has identified unpaved areas associated with trucking and warehousing adjacent to Route 66/Cajon Blvd. as a high traffic

⁸⁸ San Joaquin Valley Air Pollution Control District Rules 8061— Paved and Unpaved Roads, August 2004 and 8071 – Unpaved Vehicle and Equipment Traffic Areas, September 2004

⁸⁹ Imperial County Air Pollution Control District Rule 214.2 – Paving Unpaved Roads Emission Reduction Credits, April 2017 <https://apcd.imperialcounty.org/wp-content/uploads/2020/01/1RULE214-2.pdf>

⁹⁰ South Coast AQMD Final Paving Project Plan ECV, September 2022 <http://www.aqmd.gov/docs/default-source/ab-617-ab-134/steering-committees/eastern-coachella-valley/final-ecv-paving-project-plan.pdf?sfvrsn=8>

unpaved area that may benefit from paving. An example of an unpaved surface in the Basin that is currently being used by trucks for parking is provided in Figure III-3.

**FIGURE III-3
UNPAVED TRUCK LOT IN TORRANCE, CA**

The method of implementation of this measure may include regulatory or incentive-based approaches. The Road Paving Plan for the ECV may offer a blueprint for funding paving opportunities in 617 communities within the Basin through incentives, but regulatory requirements may be necessary in non-617 areas or where incentive funding is otherwise unavailable.

Economic Feasibility

The cost projections of paving unpaved areas vary due to materials used for paving, be it asphalt, concrete, or some combination, and the need for striping, curbing, and other improvements. The Fugitive Dust Handbook published by the Western Regional Air Partnership estimates the costs of paving one mile of unpaved road at \$44,100/mile-year with an estimated useful life of 25 years; a similar cost estimate for paving unpaved lots \$0.23/square foot-year for a useful life of 25 years, though these costs have likely increased since publication.⁹¹ CARB's Unpaved Road Dust, Non-Farm Roads Methodology estimated the total unpaved city and county road miles for the Basin at 167.3 miles, though 'high-traffic' and adjacency to AB 617 communities were not limiting factors in these estimates.⁹² Using these figures, a high cost

⁹¹Western Regional Air Partnership Fugitive Dust Handbook, 2006
https://www.wrapair.org/forums/deif/fdh/content/FDHandbook_Rev_06.pdf

⁹² California Air Resources Board Miscellaneous Process Methodology 7.10, Unpaved Road Dust, Non-Farm Roads, 2012 https://ww3.arb.ca.gov/ei/areasrc/fullpdf/full7-10_2012.pdf

estimate for paving the total unpaved city and county land in the Basin would be approximately \$184 million, though again these are total miles not ‘high-traffic’ miles, so the total unpaved lot area that would be considered by this PCM would be significantly smaller. This methodology estimates that the tons of PM/year reductions of paving the total road miles at 553.3 tons/year, or 1.52 tpd for an estimated cost effectiveness figure of \$13,334/ton. If only 10 percent of the road miles is paved this could result in a reduction of 55 tons/year of PM. While most unpaved roads are in public jurisdictions, many unpaved lots are private land and this distinction will be key to implementation of this PCM, as well defining high-traffic and distance to affected populations or AB 617 adjacency.

As the surface area of private unpaved high-traffic lots in the Basin is unknown, any incentive funding or cost-effectiveness estimates for the total unpaved area that this PCM may address is not known, and this uncertainty presents a barrier to feasibility. In addition, this PCM must be considered in the context of climate-related drought conditions and heatwaves frequently experienced in the Basin. Paving surfaces that would otherwise allow for underground aquifers to replenish during rainstorms must be acknowledged as a potential cost when assigning cost-effectiveness or designating areas for applicability to this PCM. Paving unpaved surfaces, especially in urban areas, also creates heat island effects resulting in higher temperatures than outlying areas. In densely urbanized areas, paved roads absorb and re-emit the sun’s heat more than natural landscapes becoming “islands” of higher temperatures relative to outlying areas. The costs of less permeable areas for surface drainage and heat island effects are unknown at this time. Therefore, South Coast AQMD has determined that this PCM requires further evaluation before committing to an adoption schedule and emission reductions.

Summary Table

Type of Analysis	Emission Reduction	Technological Feasibility	Economic Feasibility	Feasible Measure
BACM/BACT	TBD	<u>Yes</u> Feasible	No	No
Additional feasible measure		<u>Yes</u> Feasible	No	No
MSM		<u>Yes</u> Feasible	No	No

Other Considerations

South Coast AQMD has determined that further evaluation is required prior to implementing this control measure. Control measure BCM-19 proposes to develop an inventory of unpaved roads and parking lots within urban areas in the Basin and assess the suitability for paving. The proximity to AB 617 communities will be considered.

Potential Control Measure 14 - PM Controls for Industrial and Commercial Combustion Processes

Target Pollutant

PM_{2.5}

Synopsis

This measure is based on U.S. EPA's Menu of Control Measures, which lists various control technologies (e.g., electrostatic precipitators, Venturi scrubbers, and fabric filters) for large heaters, boilers, and generic industrial combustion processes. Due to the South Coast Air Basin's "extreme" nonattainment status for all ozone standards, South Coast AQMD is required to implement clean fuels for boilers pursuant to CAA Section 182(e)(3). U.S. EPA most recently approved the clean fuels for boilers compliance demonstration as meeting applicable requirements for the 2015 ozone standard.⁹³ As implemented by Rules 1146, 2002, 2004, and 1303, the use of solid fuels, residual oil, and diesel for boilers is effectively prohibited. As a result, industrial and commercial combustion processes in the South Coast Air Basin typically burn natural gas or process gas, which is estimated to reduce over 90 percent of PM_{2.5} emissions compared to residual oil.⁹⁴

Staff identified only one commercial application of stationary source diesel combustion in the Basin, which are engines that supply emergency backup power. All such engines > 50 horsepower are regulated by Rule 1470. Furthermore, new or modified units with ≥ 1,000 horsepower compression ignition engines are required to meet updated Lowest Achievable Emissions Rate (LAER) and BACT guidelines which require that the units achieve U.S. EPA's Tier 4 Final emission standards.⁹⁵ Existing Tier 2 units can achieve Tier 4 Final emission limits through the use of Diesel Particle Filters (DPF) and SCR.

This measure seeks to examine the feasibility of requiring further PM_{2.5} exhaust controls for natural gas and diesel fueled stationary source combustion processes.

Potential Emission Reduction

The 2030 baseline inventory is 5.20 tpd of PM_{2.5} for this source category.

Emission reductions cannot be estimated since emission reductions are already achieved in practice via implementing LAER and BACT requirements and existing rules.

Technological Feasibility

Natural gas is one of the cleanest burning of the commonly used fossil fuels (such as coal and oil) or biomass (such as wood and straw). PM emissions are negligible with natural gas fired boilers and heaters because of the low sulfur (less than 0.1 percent sulfur) and low ash content. PM emissions from natural gas combustion include both "filterable" and "condensable" portions of PM. Filterable PM is the portion of total PM that exists in the stack in either the solid or liquid state and can be captured by conventional PM control device such as filters, cyclones, ESPs or scrubbers. Condensable PM is the portion of the total PM that exists in vapor phase at stack conditions but condenses into PM in the cooler ambient air.

⁹³ 88 FR 29539

⁹⁴ <https://pm25.harcresearch.org/assets/FinalReport.pdf>

⁹⁵ <http://www.aqmd.gov/docs/default-source/Agendas/Governing-Board/2022/2022-sept2-030.pdf?sfvrsn=6You>

Condensable PM is composed of organic and inorganic compounds and of submicron size. For industrial and commercial boilers, condensable PM has the same order of magnitude emission rates as filterable PM.⁹⁶

There are limitations that make it technologically infeasible to install a PM control device for industrial and commercial natural gas combustion processes. First, filterable PM emissions from natural gas combustion are typically low to negligible because of the low sulfur and ash content and thus, installing a control equipment would not result in a significant reduction in PM_{2.5} emissions. Second, condensable PM exists as a gas in the stack and would not be effectively captured by bag filters or ESPs. Staff is not aware of PM_{2.5} controls being required or achieved in practice elsewhere in the United States for natural gas fired heaters and boilers.

Stationary emergency diesel combustion engines are used only for emergency purposes, such as backup power generation. Stationary emergency diesel engines are required to be certified to meet Tier 3 and Tier 4 emission limits based on the engine size, model year, and application pursuant to the U.S. EPA's National Emission Standards for Hazardous Air Pollutants (NESHAP) for stationary reciprocating internal combustion engines.⁹⁷ Stationary emergency diesel combustion engines with $\geq 1,000$ horsepower are already subject to meeting updated LAER through BACT as required by Regulation XIII – New Source Review. Since these stationary emergency combustion engines are already required to meet the LAER Tier 4 Final emissions standards and are addressed by BACT, there is no further potential for reductions and therefore, further PM exhaust control is technologically infeasible.

Economic Feasibility

Due to low to negligible emission reduction potential with a PM control device for natural gas fired boilers and heaters, installing a PM control device may not be cost-effective. Due to little to no potential for further PM reductions from stationary emergency diesel engines, PM control for these operations is not cost-effective.

Summary Table

Type of Analysis	Emission Reduction	Technological Feasibility	Economic Feasibility	Feasible Measure
BACM/BACT	N/A	No	No	No
Additional feasible measure		No	No	No
MSM		No	No	No

Staff is not aware of this control measure having been implemented in another nonattainment area or having been achieved in practice in another state for natural gas fueled boilers and heaters. This PCM therefore does not meet U.S. EPA's definition of MSM. Staff also reviewed U.S. EPA's Technical Support

⁹⁶ https://www3.epa.gov/ttn/chief/old/ap42/ch01/s04/final/c01s04_oct1996.pdf

⁹⁷ <https://www.epa.gov/stationary-engines/fact-sheet-final-amendments-emission-standards>

Document (TSD) for the San Joaquin Valley contingency measures Federal Implementation Plan (FIP).⁹⁸ In the infeasibility justification TSD, U.S. EPA notes that “there are no known add-on particulate matter control devices in use” for natural gas fired boilers, steam generators, and process heaters and that New Source Performance Standards (NSPS) typically do not set particulate matter limits for natural gas-fired units. U.S. EPA did not consider this to be a potential control measure in the FIP.

Potential Control Measure 15 - Lowering NOx Emission Limits for Boilers, Steam Generators, and Process Heaters

Target Pollutant

NOx

Synopsis

South Coast AQMD Rule 1146 (Emissions of Oxides of Nitrogen from Industrial, Institutional and Commercial Boilers, Steam Generators, and Process Heaters; Amended December 4, 2020) establishes NOx emission limits for boilers, steam generators, and process heaters equal to or greater than 5 million British thermal units per hour (MMBtu/hr) rated heat input capacity. San Joaquin Valley APCD Rule 4320 (Advanced Emission Reduction Options for Boilers, Steam Generators, and Process Heaters Greater than 5.0 MMBtu/hr; Amended December 17, 2020) has more stringent NOx emission limits than South Coast AQMD Rule 1146 for boilers, steam generators, and process heaters greater than or equal to 5 MMBtu/hr. For natural gas-fired boilers between 5 and 20 MMBtu/hr, the NOx limit is 5 ppm in Rule 4320, while the corresponding NOx limits are 7 to 9 ppm via ultra-low NOx burner (ULNB) in Rule 1146. In addition, for natural gas-fired units that are greater than 20 MMBtu/hr, the NOx limit is 2.5 ppm in Rule 4320. This limit is lower than the one for South Coast, which is a NOx limit of 5 ppm via selective catalyst reduction (SCR) for natural gas burning Group I units (greater than or equal to 75 MMBtu/hr) and Group II units (greater than or equal to 20 and less than 75 MMBtu/hr). Rule 4320 has an option for facilities to pay an annual emission mitigation fee in lieu of meeting the NOx limits specified in the rule, until the NOx limits can be met. While Rule 4320 provides the flexibility to comply through mitigation fees, Rule 1146 includes mandatory emission limits.

Potential Emission Reduction

Estimated emission reductions are TBD.

⁹⁸ <https://www.regulations.gov/document/EPA-R09-OAR-2023-0352-0034>

Technological Feasibility

NO_x emissions from boilers, steam generators, and process heaters can be controlled with combustion modifications such as ULNB system or with post-combustion controls such as SCR. SCR is used to control NO_x emissions from combustion sources such as boilers and process heaters. ~~SCR~~ uses a precious metal catalyst that selectively reduces NO_x in the presence of ammonia. However, incomplete reactions of NO_x and ammonia result in emissions of unreacted ammonia (also known as ammonia slip). Depending on the type of combustion equipment utilizing SCR technology, the amount of ammonia slip can vary between less than 5 ppm when the catalyst is fresh and 20 ppm at the end of the catalyst life. SCR technology is considered to be ~~a Best Available Retrofit Control Technology (BARCT)~~, if cost-effective, for controlling NO_x emissions from existing combustion sources such as boilers and process heaters. SCR technology is scalable and generally utilized for units greater than or equal to 1020 MMBtu/hr due to capital and operating costs associated. Based on the information obtained through vendor discussions, achieving 5 ppm NO_x limit with an ULNB without a SCR is feasible only for certain applications such as Group III units and for new installations, and an SCR system would be needed to achieve a NO_x limit below 5 ppm. Staff met with ClearSign™, a manufacturer of next generation ULNB technology as a potential option for achieving below a 5 ppm NO_x level with ULNB only. The vendor stated that a 2.5 ppm NO_x level can potentially be achieved in smaller units less than 20 MMBtu/hr that do not have varying fuel composition such as a firetube boiler using natural gas – these small boilers typically operate around 300 °F. It may not be feasible for units that operate at higher temperatures to perform lower than 5 ppm. Based on information provided and equipment surveyed, 7 to 9 ppm is a feasible NO_x target with ULNB technology for Group I and II units. Other factors such as whether the unit is natural draft, force draft, fuel composition, operating temperature, and the number of burners will impact the NO_x levels that can be feasibly achieved. There is currently no existing ULNB technology available that can solely achieve a 2.5 ppm NO_x limit for Group I and II units. A combination of SCR and ULNB are the only technologies that can potentially achieve a 2.5 ppm NO_x level consistently. In order for Group I and II to achieve a sub 5 ppm NO_x level, the units will need to be evaluated for ULNB and SCR. Units in the size range typically have more than one burner and will have a higher cost than Group III units. The higher cost of NO_x control will impact the overall cost-effectiveness.

The NO_x emission limit specified in Rule 1146 for natural gas-fired Group I units (i.e., units greater than or equal to 75 MMBtu/hr) is 5 ppm, which is met with the use of SCR. In addition, existing permitted, natural gas-fired Group II units (i.e., units between 20 and 75 MMBtu/hr) in South Coast AQMD are equipped with SCR. Based on the information obtained through vendor discussions, it is potentially feasible for some retrofit units to meet a NO_x limit of 4 ppm or less through SCR control. However, there are several technical limitations for SCR retrofits to meet 4 ppm or less, such as the age, flow, and size of the catalyst bed of the existing SCR system. Another technical limitation is a potentially higher ammonia slip may occur to achieve a lower NO_x limit. The typical ammonia slip permit limit on the existing SCR system is at 5 ppm. The existing catalyst bed might not be large enough to comply with both the lower NO_x limit and the 5 ppm ammonia slip permit limit. For example, NO_x emissions of 2.5 ppm could be potentially feasible for some units, but the level of ammonia slip might also be higher (i.e., 10 ppm). The most significant constraint is the inadequate safety margin between the permitted limit and the actual emissions to account for fluctuations in external factors, such as ambient temperature or fuel heat input (i.e., gas Btu).

For natural gas-fired Group III units between 5 and 20 MMBtu/hr, the NOx emission limits specified in South Coast AQMD Rule 1146 are 7 to 9 ppm, which are primarily achieved through the use of ultra-low NOx burners. Based on the information obtained through vendor discussion, ULNB replacements on existing units could potentially meet 7 ppm or less and achieving the 5 ppm NOx limit without SCR is only feasible for certain applications and for new installations. Therefore, achieving a NOx limit of 5 ppm as specified in San Joaquin's rule would not be feasible and/or cost-effective for burner retrofits of all existing units.

San Joaquin Valley APCD Rule 4320's Tier 2 NOx limits require units between 5 and 20 MMBtu/hr input rating to meet 5 ppm and units with greater than a 20 MMBtu/hr input rating to meet 2.5 ppm by December 21, 2023, with an option to comply with a mitigation fee. In San Joaquin Valley, a very small subset of the universe between 5 and 20 MMBtu/hr is currently permitted with a NOx emission limit of 5 ppm. In addition, only one unit is currently permitted with a NOx emission limit of 2.5 ppm, which is equipped with low NOx burners and an SCR system. According to San Joaquin Valley APCD's final draft staff report,⁹⁹ the 5 ppm and 2.5 ppm NOx limits in Rule 4320 may be not achievable for all units due to space limitations and economic considerations. Most affected units have typically had several layers of controls and can only reach these new limits with post-combustion controls including SCR. Therefore, both 5 ppm and 2.5 ppm NOx emission limits are rather considered technology-forcing limits and in lieu of meeting these technology-forcing limits, facility operators can pay an annual emission mitigation fee until their units become ready to comply with the limits.

Based on the staff's analysis as well as the information from San Joaquin Valley's staff report, staff concluded that achieving the emission limits of 5 ppm or lower (e.g., 2.5 ppm) is not available for all applicable units in this source category in South Coast AQMD and thus, is not a technologically feasible measure. However, burner manufacturers such as ClearSign™ are currently in development of next generation ULNB replacements for Group I and Group II units that can potentially achieve sub 5 ppm NOx levels at a much lower cost. The next generation ULNB technology is not commercially available for Group I and Group II units at the moment. Proposed Control Measure L-CMB-02 addresses emissions from boilers subject to Rule 1146 as part of the 2022 AQMP. Staff will continue to monitor and assess feasibility of obtaining a lower NOx limit for boilers which is to be addressed as part of L-CMB-02.

Economic Feasibility

Based on vendor feedback and estimates, the most-cost-effective options to meet a NOx level below 5 ppm without ammonia is next generation ULNB technology; this technology is currently not commercially available for Group I and Group II units. The current technology to achieve a NOx level below 5 ppm will require a combination of ULNB and SCR technologies or replacement with a brand-new unit which may not be feasible or cost-effective for all applications. To be determined once the lower emission limits become technologically feasible to be implemented for this source category.

Summary Table

Type of Analysis	Emission Reduction	Technological Feasibility	Economic Feasibility	Feasible Measure
BACM/BACT	TBD	Not Feasible	To Be Determined	No
Additional feasible measure		Not Feasible	To Be Determined	No
MSM		Not Feasible	To Be Determined	No

**South Coast Air Basin Attainment Plan for the 2012
Annual PM_{2.5} Standard**

Appendix III

**ATTACHMENT A: EVALUATION OF SOUTH COAST AQMD
RULES**

ATTACHMENT A-1

EVALUATION OF SOUTH COAST AQMD RULES AND REGULATIONS – PM RULES

Rule No.	Rule Title	Current Rule Requirements	Other Agencies' Rules and Federal Guidance ^a That Are More Stringent	BACM Evaluation
404	Particulate Matter - Concentration (Amended 2/7/86)	Atmospheric discharge from any source is required to meet the PM limits varying from 0.01 gr/dscf to 0.19 gr/dscf depending on exhaust flow rates.	Bay Area, Regulation 6, Rule 1 (Adopted 8/1/18) contains a maximum PM limit of 0.15 gr/dscf. There are differences in the applicability of this rule compared to Rule 404.	South Coast AQMD Rule 404 varies in stringency when compared to other Districts' requirements. Overall, Rule 404, when considered with Rule 405, meets BACT.
405	Solid Particulate Matter – Weight (Amended 2/7/86)	Atmospheric discharge from any source is required to meet the PM limits varying from 0.45 kg/hr to 13.6 kg/hr depending on process weight.	n/a ^b	Meets BACT.
444	Open Burning (Amended 7/12/13)	Contains requirements and prohibitions for open burning to minimize emissions and smoke impacts to the public; allows open burning on permissive burn days, provided a permit and burn authorization is obtained; establishes burn plan requirements for prescribed burns; sets daily maximum burn acreage for agricultural and prescribed burning.	San Joaquin Valley Rule 4103 (Amended 4/15/10) contains additional best management practices compared to Rule 444 such as best management practices to control open burning of weeds. Bay Area, Reg 5, sets requirements for open burning, and forbids recreational burning during curtailment periods.	In its TSD for the approval of Rule 444 into the California SIP published in 2013, EPA determined that with the exception of provisions about banning the burning of specific crops, Rule 444 is generally as stringent as or more stringent than analogous rules in other California Districts. Controls that address agricultural burning emissions are considered in the Control Measure Assessment section. Overall, Rule 444 provides BACT level of control for this source category.
445	Wood-Burning Devices (Amended 10/27/20)	No wood-burning device is allowed in any new development, unless it is a U.S. EPA certified wood-burning heater, a pellet-fueled wood-burning heater, a masonry heater, or a dedicated gaseous-fueled fireplace. PM2.5 mandatory burning curtailment (no-burn day) is declared in area < 3,000 ft above mean seal level and Basin-wide if daily PM2.5 is forecast to exceed 30 µg/m ³ or an applicable concentration as set forth in PM2.5 Contingency Measures during wood-burning season from November to February. If the Basin fails to meet RFP requirement, meet any quantitative milestone, submit a quantitative milestone report, or attain the applicable PM2.5 standard by attainment date, seasonal wood-burning curtailment threshold could go down as low as 26 µg/m ³ . Rule does not apply to: residential/commercial properties where a wood-burning device is the sole source of heat; a low income household; residential/commercial properties with no existing natural gas service within 150 ft of the property line; residential/commercial properties located ≥ 3,000 ft AMSL; or ceremonial fires exempted under Rule 444.	San Joaquin Valley Rule 4901 (amended 6/20/19) effective 1/1/20, prohibits sale or transfer of a real property that has a wood-burning heater unless it is either EPA Phase II certified, is a pellet-fueled wood-burning heater exempt from EPA certification, or is rendered permanently inoperable and removed from the property. Effective 1/1/20, remodel of wood-burning fireplace or chimney where total cost exceeds \$15,000 and local building permit is required, shall install only a gas-fueled, electric, exempt, or EPA certified wood burning heater at the time of installation.	Rule 445 does not contain resale and remodel provisions as does SJVAPCD Rule 4901. Staff thoroughly evaluates these and other provisions in Appendix III.

Appendix III: Attachment A – Evaluation of South Coast AQMD Rules

Rule No.	Rule Title	Current Rule Requirements	Other Agencies' Rules and Federal Guidance ^a That Are More Stringent	BACM Evaluation
1117	Emissions from Container Glass Melting and Sodium Silicate Furnaces (Amended 6/5/20)	There are no PM10 emission limits in Rule 1117.	San Joaquin Valley Rule 4353 contains a PM10 emission limit of 0.20 lbs per ton glass produced for container glass and flat glass.	Staff considered introducing PM10 emission limits in Rule 1117 and the assessment can be found in the Control Measure Assessment section.
1133, 1133.1	Rule 1133 - Composting and Related Operations – General Administrative Requirements (Adopted 1/10/03) Rule 1133.1 – Chipping and Grinding Activities (Amended 7/8/11)	Rule 1133 is an administrative rule that requires composting, chipping, and/or grinding facilities to register with the District. These facilities provide information such as types and amounts of feedstocks produced, and a description of the processes used at the facility. This information is updated annually. Rule 1133.1 establishes holding or processing time requirements for green waste and food waste chipping and grinding activities. The rule's objective is to prevent inadvertent decomposition occurring during chipping and grinding activities.	n/a ^b	Rule 1133.1 was amended in 2011 to better manage stockpile operations associated with chipping and grinding activities, which is to be consistent with current greenwaste material processing requirements established in Title 14 of the California Code of Regulations. Rule 1133.1 meets BACT.
1137	PM10 Reduction From Woodworking Operations (Adopted 2/1/02)	Require that woodworking operations send sawdust emissions either directly to a baghouse filter, or to a pneumatic conveyance device that leads to a baghouse filter.	n/a ^b	Meets BACT.
1138	Control Of Emissions From Restaurant Operations (Adopted 11/14/97)	Control Of Emissions From Restaurant Operations (Adopted 11/14/97)	Ventura Rule 74.25 (Adopted 10/12/04) has equivalent requirements as in Rule 1138. Bay Area Rule 2 of Regulation 6 (12/5/07) has emission standards of 0.74 lbs PM10 and 0.32 lbs VOC per thousand pounds of meat cooked for all chain-driven charbroilers; 1.0 lbs PM10 per thousand pounds of meat cooked for all under-fired charbroilers with combined total grill surface area of at least 10 square feet. San Joaquin Rule 4692 requires catalytic oxidizers for chain-driven charbroilers cooking 400 pounds of meat or more per week. This threshold is more stringent than Rule 1138 which applies to chain-driven charbroilers cooking 875 pounds of meat or more per week. Rule 4692 also requires that catalytic oxidizers achieve an 86% VOC and 83% PM reduction. Finally, Rule 4692 requires registration and reporting requirements for under-fire d charbroilers.	Most BAAQMD under-fired charbroiler facilities are too small to trigger the under-fired charbroiler requirements. The lower applicability threshold in SJVAPCD Rule 4692 is evaluated in the Control Measure Assessment section.
1140	Abrasive Blasting (Amended 8/2/85)	Set standards for the abrasives and require a visible emission evaluation to determine the impact of abrasive blasting operations on visibility.	n/a ^b	Rule 1140 is substantively similar to the California Code of Regulations, Title 17, Subchapter 6 — Abrasive Blasting provisions, which have been adopted by most California Air Districts. State law prohibits more stringent requirements. As such, Rule 1140 meets BACT.
1155	Particulate Matter Control Devices (Amended 5/2/14)	PM standards for PM control devices at 0.01 gr/dcsf for existing large baghouses >7500 square feet and best operational practices to reduce PM emissions.	n/a ^b	Meets BACT.

Appendix III: Attachment A – Evaluation of South Coast AQMD Rules

Rule No.	Rule Title	Current Rule Requirements	Other Agencies' Rules and Federal Guidance ^a That Are More Stringent	BACM Evaluation
1156	PM10 Emission Reductions from Cement Manufacturing Facilities (Amended 3/6/09)	PM standards for PM control devices (0.01 gr/dcsf for existing and 0.005 gr/dcsf for new devices) and best operational practices to reduce PM emissions from aggregate and related operations	n/a ^b	Meets BACT.
1157	PM10 Emissions Reductions from Aggregate and Related Operations (Amended 9/8/06)	Good operational practices to reduce PM emissions from aggregate and related operations. Establish source specific performance standards (no dust emissions exceeding 20 percent opacity, or no dust emissions exceeding 50 percent opacity, or no dust plume beyond 100 feet from any emission source, etc.) and specifying operational PM10 controls for various types of equipment, processes, storage piles, internal roadways at aggregate and related operations, and track-out of materials onto paved public roads	EPA promulgated standards for new hot mix asphalt facilities in Title 40, Chapter I, Part 60, Subpart I of the Code of Federal Regulations (40 CFR Part 60, Subpart I). Subpart I assigns a 20 percent opacity limit and a 90 mg/dscm (micrograms/dry standard cubic meter) PM content for fugitive emissions.	In its TSD for the approval of Rule 1157 into the California SIP published in 2011, EPA determined that Rule 1157 generally had the most stringent requirements and concluded that Rule 1157 fulfills BACM. Overall, Rule 1157 is as stringent as or more stringent than the other Districts' rules and meets the BACT requirements for this source category.
1186	PM10 Emissions from Paved and Unpaved Roads, and Livestock Operations (Adopted 7/11/08)	Requires good management practice such as clean-up of spills on public roadways, post-event street cleaning, routine sweeping using certified street sweeping equipment, new or widened roads to have improved road shoulders and treatment of livestock feed access lanes and cessation of hay grinding activities during high winds, etc.; Establish unpaved road treatment schedule for local jurisdictions in the Basin.	SJVAPCD Rule 8061 requires municipalities to sweep paved roads at least once per month with PM10 efficient units. For unpaved roads, on any unpaved road segment with 26 or more AADT, the owner/operator shall limit visible dust emission to 20% opacity and comply with the requirements of a stabilized unpaved road, or shall implement an APCO-approved Fugitive PM10 Management Plan; Within an urban area, requires all new roads to be paved.	In its TSD for the approval of Rule 1186 into the California SIP published in 2011, EPA determined that the requirements to ensure continued compliance added in the 2008 amendment further strengthens the SIP-approved version of this rule, which was determined to meet the BACM provisions. For the majority of the categories, Rule 1186 is as stringent as or more stringent than the other Districts' rules and provides BACT level of control. Potential measures to further reduce paved road dust emissions are considered in the Control Measure Assessment section.

^a Other agencies' rules and regulations amended/adopted before March 2023 are included in this updated BACM evaluation.

^b There are no analogous requirements in other air agencies that are more stringent than the South Coast AQMD rule being evaluated.

ATTACHMENT A-2

EVALUATION OF SOUTH COAST AQMD RULES AND REGULATIONS – NO_x RULES

Rule No	Rule Title	Current Rule Requirements	Other Agencies' Rules and Federal Guidance ^a That Are More Stringent	BACM Evaluation
476	Steam Generating Equipment (Amended 10/8/76)	For equipment with maximum heat input rate > 50 MMBTU/hr, NO _x emission limits are 125 ppm at 3% O ₂ on gas-fired equipment and 225 ppm at 3% O ₂ on liquid or solid-fired equipment, averaged over 15 minutes. In South Coast AQMD, one facility (Long Beach City SERFF) has 3 combustors subject to NO _x limit of 150 ppm (24-hr average) per 40 CFR Part 60 Subpart Ea and Eb.	Maryland (Section 26.11.08 Control of Incinerators) NO _x emission limits for two applicable facilities are 140 and 150 ppm respectively at 24-hr average, and 105 and 145 ppm respectively at 30-day average.	Steam generating equipment in South Coast AQMD is subject to requirements similar to those in Maryland on a 24-hr average basis (140 to 150 ppm in Maryland vs. 150 ppm in South Coast). The 2022 AQMP includes control measure L-CMB-09 which will further reduce NO _x emissions at the Long Beach City SERFF with implementation scheduled by 2030. This measure is included in the PM _{2.5} Plan as BCM-07.
1110.2	Emissions from Gaseous- and Liquid-Fueled Engines (Amended 11/1/19)	The following NO _x limits apply to all stationary and portable engines over 50 bhp. Stationary, non-emergency engines and biogas (landfill and digester gas) engines: • 11 ppm NO _x New non-emergency engines with electrical generators: • 0.07 lbs NO _x /MW-hr (or 2.5 ppm NO _x) General low-usage engines: • 36 ppm NO _x , engines ≥500 hbp • 45 ppm NO _x , engines <500 hbp Low-usage biogas engines: • 36 x ECF ppm NO _x , engines ≥500 hbp • 45 x ECF ppm NO _x , engines <500 hbp	n/a ^b	Meets BACT.
1111	Reduction of NO _x Emissions from Natural-Gas-Fired, Fan-Type Central Furnaces (Amended 10/1/21)	The maximum NO _x limit from fan-type central furnaces is 40 ng/J. On or after 10/1/12, NO _x limit is 14 ng/J for residential and commercial fan-type central furnaces. Mobile home furnaces NO _x limit is lowered to 14 ng/J by 10/1/18. Alternate compliance plan with mitigation fees with varying compliance dates.	BAAQMD Regulation 9, Rule 4 establishes a zero NO _x emission limit for new natural gas-fired space heaters with a capacity < 175,000 Btu/hr beginning in 2029.	BAAQMD's zero emission limits are further evaluated in Appendix III.
1117	Emissions from Container Glass Melting and Sodium Silicate Furnaces (Amended 6/5/21)	The following emission limits apply. • 0.75 lbs NO _x /ton of glass pulled averaged over 30 days • 0.50 lbs NO _x /ton of product pulled averaged over 30 days for sodium silicate furnaces • 30 ppmv NO _x at 3% O ₂ or 0.036 lb/MMBTU of heat for auxiliary combustion equipment	n/a ^b	Meets BACT/BACM.
1118	Control of Emissions from Refinery Flares	• Operators must operate all flares in a manner that minimizes flaring	n/a ^b	Meets BACT/BACM.

Appendix III: Attachment A – Evaluation of South Coast AQMD Rules

Rule No	Rule Title	Current Rule Requirements	Other Agencies' Rules and Federal Guidance ^a That Are More Stringent	BACM Evaluation
	<u>(Amended April 5, 2024)</u>	<ul style="list-style-type: none"> • For hydrogen clean service flares, establishes a NOx performance target 0.3 lbs. per million standard cubic feet of hydrogen production capacity • LPG flares are required to comply with a throughput threshold of 15,000 MMBtu/year • Requires payment of mitigation fees and submission of a Flare Minimization Plan is performance targets are exceeded 		
1118.1	Control of Emissions from Non-Refinery Flares (Adopted 1/4/19)	Flare gas NOx emission limits range from 0.018 lbs/MMBtu for produced gas to 0.025 lbs/MMBtu for major digester gas and landfill gas. All other flare gas including minor digester gas is required NOx emission limits at 0.06 lbs/MMBtu. Organic liquid storage has NOx emission limit at 0.25 lbs/MMBtu and organic liquid loading has NOx limit at 0.034 lbs/1,000 gallons loaded.	n/a ^b	Meets BACT/BACM.
1121	Control of Nitrogen Oxides from Residential Type, Natural Gas-Fired Water Heaters (Amended 9/3/04)	<p>For natural gas-fired water heaters rated <75,000 Btu/hr, NOx emission limits:</p> <ul style="list-style-type: none"> • 55 ppm for mobile home • 30 ppm for residential home • 15 ppm for water heaters ≤50 gallons 	BAAQMD Regulation 9, Rule 6 establishes zero NOx emission limits.	BAAQMD's zero emission limits are further evaluated in Appendix III.
1134	Emissions of Oxides of Nitrogen from Stationary Gas Turbines (Amended 2/4/22)	<p>Requirements that will remain in effect until 2024:</p> <p>Standard = Reference Limit x (Unit Efficiency/25%), where reference limit depends on size of units, varying from 9 ppm to 25 ppm.</p> <p>New emission limits become effective 1/1/24:</p> <ul style="list-style-type: none"> • Liquid fuel turbines located on Outer Continental Shelf (OCS): 30 ppm NOx / 5 ppm NH3 • Natural gas, combined cycle turbine: 2 ppm NOx / 5 ppm NH3 • Natural gas, simple cycle turbine: 2.5 ppm NOx / 5 ppm NH3 • Produced gas: 9 ppm NOx / 5 ppm NH3 • Produced gas turbine located on OCS: 15 ppm NOx / 5 ppm NH3 <p>Other: 12.5 ppm NOx / 5 ppm NH3.</p>	San Joaquin Rule 4703 (Amended 9/20/07) has standards from 5–50 ppm depending on size of units. Combined cycle units > 10 MW has limit of 3 ppm.	<p>NOx emissions range has a lower limit in San Joaquin Rule 4703 (5 ppm) than South Coast Rule 1134 (9 ppm), while the upper limit is lower in South Coast Rule 1134 (25 ppm) than San Joaquin Rule 4703 (50 ppm). Therefore, for the majority of the categories, Rule 1134 is as stringent as the other District's rules.</p> <p>In early 2019, South Coast AQMD staff performed a BARCT analysis based on technological and economic feasibility, and established BARCT emission limits for equipment subject to Rule 1134. As such, Rule 1134 reflects up to date BARCT requirements, which is equivalent to BACT.</p>
1135	Emissions of Oxides of Nitrogen from Electricity Generating Facilities (Amended 1/7/22)	Electricity generating facilities (EGF) have NOx emission limits at 5 ppm for boilers (at 3% O2), 2 ppm for combined cycle gas turbines, and 2.5 ppm for simple cycle gas turbines (at 15% O2) that are fired on natural gas. Internal combustion engines firing diesel limit NOx emissions at 45 ppm (at 15% O2). All NOx limits are 60 minute averages.	n/a ^b	Meets BACT.
1146, 1146.1	Rule 1146 - Emissions of Oxides of Nitrogen from Industrial, Institutional, and	Rule 1146 NOx emission limits for industrial/commercial boilers, steam generators, and process heaters ≥ 5 MMBtu/hr:	San Joaquin Valley Rules 4306 and 4320 (Amended 12/17/20) require NOx limits for boilers, steam	Rules 1146/1146.1 currently limit NOx emissions from thermal fluid heaters to 12 ppm, while the Rule 4306 Tier 2 NOx limit is 9 ppm. Based on the Rules 1146/1146.1 staff

Appendix III: Attachment A – Evaluation of South Coast AQMD Rules

Rule No	Rule Title	Current Rule Requirements	Other Agencies' Rules and Federal Guidance ^a That Are More Stringent	BACM Evaluation
	<p>Commercial Boilers, Steam Generators, and Process Heaters (Amended 12/4/20)</p> <p>Rule 1146.1 - Emissions of Oxides of Nitrogen from Small Industrial, Institutional, and Commercial Boilers, Steam Generators, and Process Heaters (Amended 12/7/18)</p>	<ul style="list-style-type: none"> • Gaseous fuel: 30 ppm • Non-gaseous fuel: 40 ppm • Landfill gas: 25 ppm • Digester gas: 15 ppm • Atmospheric units (5–10 MMBtu/hr): 12 ppm • Group I (≥75 MMBtu/hr burning natural gas): 5 ppm • Group II (≥20 & <75 MMBtu/hr with gaseous fuels) <ul style="list-style-type: none"> ▪ Fire-tube boilers with previous limits 5–9 ppm: 7 ppm ▪ All other units (with previous limits 5–12 ppm): 9 ppm ▪ All others: 5 ppm • Group III (≥5 & <20 MMBtu/hr with gaseous fuels) <ul style="list-style-type: none"> ▪ Fire-tube boilers with previous limits 9–12 ppm: 7 ppm ▪ All others: 9 ppm • Thermal fluid heaters: 12 ppm. <p>Rule 1146.1 NOx emission limits for industrial/commercial boilers, steam generators, and process heaters between 2-5 MMBtu/hr:</p> <ul style="list-style-type: none"> • Landfill gas: 25 ppm • Digester gas: 15 ppm • Atmospheric units (5–10 MMBtu/hr): 12 ppm • Fire-tube boilers: 7 ppm • Natural gas units: 9 ppm • Thermal fluid heaters: 12 ppm • All other units: 30 ppm <p>Rules 1146/1146.1's compliance dates:</p> <ul style="list-style-type: none"> • Non-RECLAIM facilities <ul style="list-style-type: none"> • 12/7/18 • 12/7/33 with a permit limit ≤ 20 ppm • 1/1/22 with a permit limit > 20 ppm • RECLAIM facilities <ul style="list-style-type: none"> ▪ 12/7/33 with a permit limit ≤ 20 ppm <p>1/1/22 with a permit limit > 20 ppm</p>	<p>generators, and process heaters ≥ 5 MMBtu/hr. Rule 4306 Tier 2 NOx limits by 2023–2029:</p> <ul style="list-style-type: none"> • Category A (>5–20 MMBtu/hr): <ul style="list-style-type: none"> ▪ Thermal fluid heaters: 9 ppm <p>San Joaquin Valley Rule 4320 (Amended 12/17/20) provides advanced emission reduction options: (1) meet the specific NOx emission limits, (2) pay an annual emissions fee, or (3) comply with low-use provision. Rule 4320 Tier 2 NOx limits are technology-forcing limits with compliance deadline by 2023:</p> <ul style="list-style-type: none"> • Category A (>5–20 MMBtu/hr): <ul style="list-style-type: none"> ▪ Fire-tube boilers: 5 ppm ▪ Thermal fluid heaters: 9 ppm ▪ All others: 5 ppm • Category B (>20 MMBtu/hr): <ul style="list-style-type: none"> ▪ Fire-tube boilers >20–75 MMBtu/hr: 2.5 ppm ▪ All others >20–75 MMBtu/hr: 2.5 ppm ▪ All others >75 MMBtu/hr: 2.5 ppm 	<p>report, an emission limit of 12 ppm was feasible for retrofits at the time of rule development, but an emission limit of 9 ppm is feasible for new burners upon replacement. For lowering the emission limit from 12 ppm to 9 ppm, the cost-effectiveness ranges from \$58,000 to \$523,000 per ton of NOx reduced based on the assumption of 10–90% operating capacity of the thermal fluid heaters at different heat capacity sizes. Therefore, due to high cost-effectiveness of a 9 ppm emission limit, the 12 ppm NOx emission limit in Rule 1146 series is considered the BARCT level of control for the thermal fluid heaters.</p> <p>In general, the emission limits in San Joaquin Valley Rule 4320 are more stringent than those in Rule 1146 for boilers >5 MMBtu/hr. The NOx limits in Rule 4320 are technology-forcing limits with an option to comply by paying an annual emission fee in lieu of meeting the limits. Because Rule 4320 provides the flexibility to comply through mitigation fees, it is not evaluated against Rule 1146, which includes mandatory emission limits. A more extensive analysis to evaluate the feasibility of these emission limits is presented in the Control Measure Assessment section.</p>
1146.2	Emissions of Oxides of Nitrogen from Large Water Heaters and Small Boilers and Process Heaters (Amended 12/7/18)	<p>Applicable to natural gas-fired water heaters, boilers, and process heaters with heat rating ≤2 MMBTU/hr. As of January 1, 2010, any Type II unit between 400,000 Btu/hr and 2 MMBtu/hr is required to meet a 20 ppm NOx limit, and as of January 1, 2012, any Type I unit (except pool heaters) ≤400,000 Btu/hr is required to meet 20 ppm NOx limit. Effective January 1, 2000, new Type I units including pool heaters are required to meet the 55 ppm NOx limit, and new Type II units are required 30 ppm NOx limit.</p>	n/a ^b	Meets BACM.

Appendix III: Attachment A – Evaluation of South Coast AQMD Rules

Rule No	Rule Title	Current Rule Requirements	Other Agencies' Rules and Federal Guidance ^a That Are More Stringent	BACM Evaluation
1147	NOx Reductions from Miscellaneous Sources (Amended 5/6/22)	<p>Multiple NOx emission limits for gas and liquid fuel fired units. For unit heat rating $\geq 325,000$ Btu/hr:</p> <ul style="list-style-type: none"> Gaseous fuel-fired equipment, including burnoff furnaces and incinerators with or without integrated afterburners, have 20-60 ppm NOx emission limits depending on application, process temperature, and implementation timeframes. Micro-turbines must achieve 9 ppmv NOx. Asphalt manufacturing must achieve 40 ppmv NOx. <p>Liquid fuel fired units are set at 40 ppm at process temperatures below 1,200 degrees Fahrenheit and 60 ppm above 1,200 degrees Fahrenheit.</p>	n/a ^b	Meets BACT.
1153.1	Rule 1153.1 - Emissions of Oxides of Nitrogen from Commercial Food Ovens (Amended 8/4/23)	Commercial in-use food ovens set Phase I NOx limits at 30 ppm, except for tortilla ovens with IR burners the NOx limit is 15 ppm. Phase II zero emission limits for certain equipment types.	n/a ^b	Meets BACT.
1179.1	Emission Reductions from Combustion Equipment at Publicly Owned Treatment Works Facilities (Adopted 10/2/20)	<p>Rule 1179.1 NOx emission limits for digester gas units at publicly owned treatment works facilities:</p> <p>1) Digester gas or dual fuel boilers/process heaters</p> <ul style="list-style-type: none"> 90% digester gas >2 MMBtu/hr: 15 ppm 100% natural gas >2 MMBtu/hr: 9 ppm 100% natural gas ≤ 2 MMBtu/hr: 30 ppm <p>2) Turbines</p> <ul style="list-style-type: none"> 60% digester gas ≥ 0.3 MW: 18.8 ppm 100% natural gas, simple cycle ≥ 0.3 MW: 2.5 ppm 100% natural gas, combined cycle ≥ 0.3 MW: 2 ppm Digester gas/dual fuel/natural gas <0.3 MW: 9 ppm <p>3) Digester gas and dual fuel engines</p> <ul style="list-style-type: none"> Engines >50 hp: 11 ppm 	San Joaquin Valley Rules 4306 and 4320 (Amended 12/17/20) require NOx limits for boilers fired on digester gas $>5-20$ MMBtu/hr to be at 9 ppm.	For boilers fired on digester gas, the NOx limit in Rule 1179.1 (15 ppm) is not as stringent as the limit in San Joaquin Valley Rules 4306/4320 (9 ppm). 2022 AQMP control measure L-CMB-08 seeks to lower the NOx limit to 9 ppm by requiring ultra-low NOx burners for digester gas fueled boilers. Staff analysis determined that L-CMB-08 cannot be feasibly implemented until after 2030.
2002	Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx) (Amended 10/5/18)	<p>Includes facility allocations for NOx for Regional Clean Air Incentives Market (RECLAIM) facilities. Each RECLAIM facility is required to have adequate RECLAIM trading credits (RTCs) to offset its quarterly and annual NOx emissions. Emission reduction target is set by decreasing level of allocations, and these RECLAIM allocations are established and updated based on Best Available Retrofit Control Technology (BARCT) emission limits.</p> <p>RECLAIM NOx emission limits for refinery boilers, heaters, and steam generators are:</p> <ul style="list-style-type: none"> <20 MMBtu/hr: 12 ppm 20–40 MMBtu/hr: 9 ppm >40 MMBtu/hr: 2 ppm 	<p>San Joaquin Valley Rule 4306 (Amended 12/17/20) requires Tier 2 NOx limits for refinery boilers, steam generators, and process heaters ≥ 5 MMBtu/hr as follows with compliance deadline by 2023:</p> <ul style="list-style-type: none"> ≤ 40 MMBtu/hr: <ul style="list-style-type: none"> Boilers: 30 ppm & 5 ppm upon replacement <p>San Joaquin Valley Rule 4320 (Amended 12/17/20) provides advanced emission reduction options, whereby either (1) meet the specific NOx emission limits, (2) pay an annual emissions fee, or (3) comply with low-use provision. Rule 4320 Tier 2 NOx limits for refinery units</p>	<p>Refinery boilers and heaters are currently regulated under RECLAIM (Regulation XX) in the South Coast AQMD. For the units ≤ 40 MMBtu/hr, NOx emission limits are at 9–12 ppm, while San Joaquin Valley Rule 4306 NOx limits are at 30 ppm and 5 ppm upon replacement at the end of the useful life of the equipment to increase the cost-effectiveness of the requirement. Therefore, the NOx limits in Rule 2002 are more stringent than in Rule 4306 for existing units. Because Rule 4320 has an option to comply through mitigation fees, it is not evaluated against Rule 2002.</p> <p>As the RECLAIM program transitions to the command-and-control regulatory structure, refinery boilers are required to meet NOx emission limits under Rule 1109.1 (Emissions of Oxides of Nitrogen from Petroleum Refineries and Related</p>

Appendix III: Attachment A – Evaluation of South Coast AQMD Rules

Rule No	Rule Title	Current Rule Requirements	Other Agencies' Rules and Federal Guidance ^a That Are More Stringent	BACM Evaluation
			<p>are technology-forcing limits with compliance deadline by 2023 as follows:</p> <ul style="list-style-type: none"> Boilers/process heaters >5–40 MMBtu/hr: 5 ppm 	<p>Operations), adopted 11/5/21. Rule 1109.1 requires boilers <40 MMBtu/hr to be 40 ppm on or before 7/1/22 and 5 ppm afterwards. These limits were determined from a comprehensive BARCT assessment that took both technological feasibility and cost-effectiveness into account. Lowering the NOx limit for refinery boilers to 30 ppm was not cost-effective. Refer to Rules 1146 and 1146.1 for the evaluation of non-refinery units. Overall, staff concludes that South Coast AQMD's RECLAIM NOx emission limits for refinery boilers and heaters are at least as stringent as San Joaquin Valley Rule 4306, and meet BACT.</p>

^a Other agencies' rules and regulations amended/adopted before March 2023 are included in this updated BACM evaluation.

^b There are no analogous requirements in other air agencies that are more stringent than the South Coast AQMD rule being evaluated.

ATTACHMENT A-3

EVALUATION OF SOUTH COAST AQMD RULES AND REGULATIONS – NH3 RULES

Rule No	Rule Title	Current Rule Requirements	Other Agencies' Rules and Federal Guidance ^a That Are More Stringent	BACM Evaluation
223	Emissions Reduction Permits From Large Confined Animal Facilities (Adopted 6/2/06)	Sets permit requirement for new and modified LCAF facilities. Specifies mitigation options by animal and facility type for: <ul style="list-style-type: none"> • Feed and silage handling, • Milk parlor operations, • Corrals and free stall barn operations, • Handling of manure and solids, • Handling of manure in liquid form • Land application of liquid or solid manure 	SJVAPCD Rule 4570 is more stringent regarding applicability than Rule 223 for milk cows, (1,000 milk cows in South Coast AQMD vs 500 milk cows in SJVAPCD), and for chickens and ducks (650,000 birds in South Coast AQMD vs. 400,000 birds in SJVAPCD). However, that is partly mitigated by South Coast AQMD Rule 1127 which has a much lower applicability thresholds of 50 or more cows, heifers and/or calves. Rule 223 also has a lower applicability for horse facilities (2,500 in South Coast AQMD vs. 3,000 in SJVAPCD). Rule 4570 sets comparable permit requirements and mitigation measures.	Staff evaluated the potential to achieve further NH3 emission reductions from livestock waste in the Control Measure Assessment section.
1127	Emission Reductions from Livestock Waste (Adopted 8/6/04)	Requires Good housekeeping practices for dairy farms with 50 or more cows, heifers and/or calves. Note: The South Coast AQMD adopted Rule 223 in June 2006 to reduce emissions for large confined animal facilities. Rule 223 includes series of best management practices that are more stringent than those required by Rule 1127.	Sacramento Rule 496 – Large Confined Animal Facilities (Adopted 8/24/06), has more stringent control and good management practices than South Coast Rule 1127 (e.g. venting to control system with at least 80% control efficiency). The more stringent requirements are targeted towards silage emissions, which is not applicable in South Coast for dry feed lot operations. SJVAPCD Rule 4565 and 4566 sets comparable permit requirements and mitigation measures. SJVAPCD 4570 has required best management practices for manure management and other areas to reduce VOC and ammonia emissions. Note that direct comparison with Rule 1127 is difficult due to the significant differences in source operations (dry feed lot in South Coast vs. flushing and lagoon operations in San Joaquin, the focus on corral waste control in South Coast AQMD vs. feed and silage and milk parlor in SJVAPCD, etc). In addition, SJV Rule 4570 applies to all types of confined animal facilities, while Rule 1127 applies only to dairies with a much lower applicability threshold.	Staff evaluated the potential to achieve further NH3 emission reductions from livestock waste in the Control Measure Assessment section.
1133.2, 1133.3	Emission Reductions from Co-Composting Operations (Adopted 1/10/03), Emission Reductions from Greenwaste Composting Operations (Adopted 7/8/11)	Various performance standards. Air pollution control must have 80% control efficiency or greater. Existing operations must reduce up to 70% baseline VOC and ammonia emissions. Baseline emission factors are 1.78 lbs VOC/ton throughput and 2.93 lbs NH3/ton throughput.	San Joaquin Rule 4565 – Biosolids, Animal Manure, and Poultry Litter Operations (Adopted 3/15/07) and Rule 4566 – Organic Material Composting Operations (Adopted 8/18/11) have various operational requirements for these operations as well as the operators who landfills, composts, or co-composts these materials. The applicability of Rules 4565/4566 is	South Coast AQMD Rule 1133.2 is more stringent than San Joaquin's Rule 4565 for larger co-composting facilities and less stringent for smaller co-composting facilities. While South Coast AQMD Rule 1133.2 requires either 70 or 80% overall emission reductions from all parts of composting process, San Joaquin's Rule 4565 requires add-on controls to apply only to the active composting phase. Rule 1133.2 also

Appendix III: Attachment A – Evaluation of South Coast AQMD Rules

Rule No	Rule Title	Current Rule Requirements	Other Agencies' Rules and Federal Guidance ^a That Are More Stringent	BACM Evaluation
		<p>Rule 1133.3 establishes operational best management practices (BMPs) for greenwaste composting operations. If the facility processes more than 5,000 tons per year of foodwaste, any active phase of composting containing more than 10% foodwaste, by weight, must use an emission control device with an overall control efficiency of at least 80% by weight of VOC.</p> <p>For operations less than 5000 tons/year, require the composting piles to be covered, watered, and turned, or operated with measures that reduce at least 40% VOC emission and 20% NH3 emissions.</p>	<p>broader than the applicability of Rule 1133.3. In addition, Rules 4565/4566 include additional mitigation measures to control VOC from composting active piles (e.g. maintain minimum oxygen concentration of 5%, moisture content of 40%-70%, carbon to nitrogen ratio of 20-1).</p>	<p>has more stringent requirements for in-vessel composting. San Joaquin's rule does not address chipping & grinding as does Rule 1133.1. Overall, Rules 1133.2 and 1133.3 are as stringent as or more stringent than other Districts' rules, and meet the BACT requirement for this source category.</p> <p>Staff evaluated the potential to achieve further NH3 emission reductions from composting in the Control Measure Assessment section.</p>

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

Executive Summary

The Clean Air Act (the Act) specifies required levels of emission controls in a State Implementation Plan (SIP), depending upon the severity of the air quality problem and amount of time in which a nonattainment area needs to meet the PM_{2.5} standard. The State has conducted this analysis for each State-regulated source category emitting direct PM_{2.5} and relevant precursors in the South Coast Air Basin (South Coast). The suite of control measures that is currently being implemented by California Air Resources Board (CARB or Board) — ~~both the current control program and new measures proposed for the South Coast~~ — satisfies the applicable Most Stringent Measures (MSM) control requirements for the 2024 12 µg/m³ annual PM_{2.5} Plan. This analysis finds that California's mobile source control program is the most stringent and far-reaching suite of mobile source control measures that is currently implemented in the nation meeting the required levels of emissions controls. Furthermore, California has committed to adopting numerous new measures for mobile sources as well as setting a zero-emission standard for residential and commercial space and water heaters, which go beyond MSM requirements and will, when it goes into effect, would be the most stringent of any state regulation of its kind for each applicable category in the U.S., and would exceed the stringency of federal requirements.

In conducting this analysis, CARB staff followed a four-step process of assessing California's control program. First, CARB staff identified mobile source and residential and commercial building appliance emissions as a significant contributor to ambient PM_{2.5} levels. Next, CARB staff identified potential control measures for each mobile source sector and the appliance sector, including an analysis of California's control program, other control measures in practice throughout the nation, control measures suggested by the public, and reconsideration of control measures that were previously considered to be infeasible (as applicable). Staff then assessed the stringency and feasibility of the potential control measures that were identified. And finally, while many of the measures identified in this analysis have already been adopted by CARB and submitted in the California SIP, additional control measures have been included in the 2022 State Strategy for the State Implementation Plan (2022 State SIP Strategy)¹ and will be commitments in the proposed South Coast SIP for the 2024 12 µg/m³ annual PM_{2.5} Plan. CARB's current control programs are already the most stringent in the country and thus meet MSM requirements; all 2022 State SIP Strategy measure commitments go beyond MSM requirements.

Given the severity of California's air quality challenges and the need for ongoing emission reductions, CARB has implemented the most comprehensive mobile source emissions control program in the nation. In aggregate, California's comprehensive suite of new vehicle and engine emission standards, in-use control measures, fuel specifications, and incentive programs for mobile sources represent the most stringent level of controls in the nation, and achieve the maximum feasible emission reductions

¹ 2022 State SIP Strategy <https://ww2.arb.ca.gov/resources/documents/2022-state-strategy-state-implementation-plan-2022-state-sip-strategy>

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

for this category. CARB's comprehensive program relies on five fundamental approaches:

- Stringent emissions standards that minimize emissions from new vehicles and equipment;
- In-use programs that target the existing fleet and require the use of the cleanest vehicles and emissions control technologies;
- Cleaner fuels that minimize emissions during combustion;
- Incentive programs that remove older, dirtier vehicles and equipment and replace those vehicles with the cleanest technologies; and,
- Driving to zero-emissions for engines and powertrains where feasible, in accordance with the Governor's Executive Order N-79-20².

Figure 1: Transition from Combustion

This multi-faceted approach has spurred the development of increasingly cleaner technologies and fuels, and achieved significant emission reductions across all mobile source sectors that go far beyond national programs or programs in other states. These efforts extend back to the first mobile source regulations adopted in the 1960s, and predate the Act of 1970, which established the basic national framework for controlling air pollution. In recognition of the pioneering nature of CARB's efforts, the Act provides California unique authority to regulate mobile sources more stringently than the federal government by providing a waiver of preemption for its new vehicle emission standards

² California Executive Order N-79-20 <https://www.gov.ca.gov/wp-content/uploads/2020/09/9.23.20-EO-N-79-20-Climate.pdf>

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

for on-road vehicles and engines under Section 209(b), and authorizations for new off-road emission standards under Section 209(e)(2). These waiver and authorization provisions preserve a pivotal role for California in the control of emissions from new motor vehicles and engines, recognizing that California serves as a laboratory for setting mobile source emission standards. Since then, CARB has consistently sought and obtained waivers and authorizations for its new motor vehicle and off-road regulations. CARB's history of progressively strengthening standards as technology advances, coupled with the waiver and authorization process requirements, ensures that California's regulations remain the most stringent in the nation.

In 1998, CARB identified diesel particulate matter as a toxic air contaminant. Since then, CARB adopted numerous regulations aimed at reducing exposure to diesel particulate matter while concurrently providing reductions in oxides of nitrogen (NO_x) from freight transport sources like heavy-duty diesel trucks, transportation sources like passenger cars and buses, and off-road sources like large construction equipment. Phased implementation of these regulations will continue to produce emission reduction benefits through 2030 and beyond, as the regulated fleets are retrofitted, and as older and dirtier portions of the fleets are replaced with newer and cleaner models at an accelerated pace.

Further, CARB and South Coast Air Quality Management District (South Coast AQMD) staff work closely on identifying and distributing incentive funds to accelerate cleanup of vehicles and engines. Key incentive programs include the Low Carbon Transportation, Air Quality Improvement Program, VW Mitigation Trust, Community Air Protection, Carl Moyer Program, Goods Movement Program, Clean Off-Road Equipment (CORE) and Funding Agricultural Replacement Measures for Emission Reductions (FARMER). These incentive-based programs work in tandem with regulations to accelerate deployment of cleaner technology.

California's programs are the most stringent in the nation for each category CARB regulates:

- California's control measures for the passenger vehicle fleet includes new vehicle emission standards, fuel specifications, and the most rigorous in-use inspection program for on-road light-and medium-duty vehicles in the country. The suite of on-road light-duty vehicle control measures included in the South Coast's plan is anticipated to achieve the maximum feasible emission reductions possible, and is comprised of the most stringent level of control measures for this category in the nation.
- California's heavy-duty on-road vehicle and engine control program is comprised of the most stringent emission standards for new engines in the nation (i.e., new vehicle tailpipe emission and evaporative emission standards; certification, testing, and verification requirements; warranty and useful life requirements, and OBD system requirements). Additionally, to reduce in-use emissions and accelerate fleet turnover to cleaner engines, California's in-use control measures include, in aggregate, the most stringent inspection and maintenance program, idling requirements, and legacy fleet requirements for on-road heavy-duty fleets

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

in the nation. Finally, California's clean diesel regulations provide the most stringent emission controls in the nation for conventional and renewable diesel fuels and diesel substitute fuels. The suite of on-road heavy-duty control measures that will be included in the South Coast's plan is anticipated to achieve the maximum feasible emission reductions possible, and is comprised of the most stringent level of control measures for this category in the nation.

- California's off-road engine and equipment control program includes the most stringent emission standards for new engines in the nation, comprehensive in-use fleet requirements to address emissions from the legacy fleets, and the cleanest off-road diesel fuel specifications in the nation. California's in-use control measures are national models for aggressive and successful efforts to reduce in-use emissions and accelerate fleet turnover to cleaner engines. In aggregate, the suite of off-road mobile source control measures that will be included in the South Coast's plan is anticipated to achieve the maximum feasible emission reductions possible, and is comprised of the most stringent level of control measures for this category in the nation.
- California's space and water heaters will include the most stringent emission standards of any state in the nation. For the first time, CARB will be setting an emission standard for space heaters and water heaters, to go into effect in 2030. CARB would adopt a statewide zero greenhouse gas (GHG) emission standard, which would have criteria pollutant co-benefits. Beginning in 2030, 100 percent of sales of new space heaters and water heaters would need to comply with the emission standard. Because no other state in the country has such a requirement, this emission standard would go beyond MSM requirements and would be the most stringent level of control measures for this category of any state in the nation.

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

Section I. Clean Air Act Requirements for Emission Control Measures

The particulate matter provisions in the Act establish a step-wise process for classifications and attainment dates:

- The first step is a Moderate area SIP, with an initial attainment date six years after the area is designated nonattainment;
- If attainment within six years is impracticable given the severity of the PM_{2.5} challenge in that area, then U.S. EPA re-classifies the area to Serious, and establishes requirements for a second SIP submittal that must show attainment within 10 years after the area was originally designated nonattainment.
- If the Serious area cannot show attainment within 10 years, the state can request an additional five-year extension if most stringent measures are in place and the State has met their obligations for the standard.

Likewise, the Act specifies a step-wise process for the required level of emission controls in a SIP, depending upon the severity of the air quality problem and amount of time a nonattainment area needs to meet the PM_{2.5} standard:

- For a Moderate nonattainment area, the required level of control is Reasonably Available Control Measures (RACM).³
- For a Serious PM_{2.5} nonattainment area, Best Available Control Measure (BACM) is the required level of control. U.S. EPA defines BACM to be the maximum degree of emission reductions achievable from a source or source category determined on a case-by-case basis considering energy, economic, and environmental impacts.⁴
- For a Serious PM_{2.5} nonattainment area for which air quality modeling demonstrates that the area cannot practicably attain by the end of the tenth calendar year (i.e. designated as “Serious with Extension”), MSM is the required level of control.⁵ U.S. EPA defines MSM as, “the maximum degree of emission reductions that has been required or achieved from a source or source category in any other attainment plans or in practice in any other states and that can feasibly be implemented in the area.”⁶ MSM is also inclusive of BACM requirements.
- For a Serious PM_{2.5} nonattainment area that has not attained by the applicable attainment date (i.e., designated as “Serious – 5% Plan”), the required level of control is also MSM.⁷

The South Coast is a Serious nonattainment area for its upcoming SIP for the 12 µg/m³ annual PM_{2.5} standard discussed in this plan and will include an extension beyond ten years.

³ RACM requirements are addressed in the Moderate SIP for the South Coast. For further information see <https://ww2.arb.ca.gov/our-work/programs/california-state-implementation-plans/nonattainment-area-plans/south-coast-air>

REQUIRED STRINGENCY OF CONTROL MEASURES

Based on the South Coast's current classification for 12 µg/m³ annual PM_{2.5} standard, Table 1 describes the level of control measures required. The control measures for this plan must satisfy U.S. EPA's increasingly stringent Most Stringent Measures (MSM) requirements.

Table 1: Stringency of Control Measures Required⁸

Standard	Classification	Type of Plan	Control Measure Requirements
12 µg/m ³ Annual (2012 Standard)	Serious with Extension	Most Stringent Measures (MSM)	Most Stringent Measures "The state shall identify, adopt, and implement the most stringent control measures that... can be feasibly implemented in the area." 40 CFR 51.1010(b)

DEFINING MOST STRINGENT MEASURES

MSM is the level of stringency required for the 12 µg/m³ annual PM_{2.5} standard. The Act defines MSM as, "any permanent and enforceable control measure that achieves the most stringent emissions reductions in direct PM_{2.5} emissions and/or emissions of PM_{2.5} plan precursors from among those control measures which are either included in the SIP for any other National Ambient Air Quality Standard (NAAQS), or have been achieved in practice in any state, and that can feasibly be implemented in the relevant PM_{2.5} NAAQS nonattainment area."⁹

U.S. EPA guidance indicates that MSM is inclusive of the requirements and process for determining BACM.¹⁰ The Act defines BACM as, "any technologically and economically feasible control measure that can be implemented in whole or in part within four years after the date of reclassification of a Moderate PM_{2.5} nonattainment area to Serious and that generally can achieve greater permanent and enforceable emissions reductions in direct PM_{2.5} emissions and/or emissions of PM_{2.5} plan precursors from sources in the area than can be achieved through the implementation of RACM on the same source."¹¹ U.S. EPA has further clarified that BACM-level of controls are:¹²

- The maximum degree of emissions reductions achievable from a source or source category, which is determined on a case-by-case basis considering energy, economic and environmental impacts;
- More stringent than RACM, but less stringent than the lowest achievable emission rate (LAER), which doesn't take into consideration the cost effectiveness of implementing a particular control measure;

⁸ The proposed South Coast SIP has been developed to provide the necessary elements for the for the 12 µg/m³ Annual PM_{2.5} Standard, for which the South Coast is classified as nonattainment. This appendix has been developed to meet a subset of these requirements; namely the requirement that staff demonstrate that the control strategies for the South Coast's plan for the 12 µg/m³ Annual PM_{2.5} Standard satisfy U.S. EPA's requirements for Serious area attainment plan control strategy requirements, as set forth in § 51.1010, for the source categories of: mobile sources, and residential and commercial building appliances.

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

- Additive to RACM, as BACM will generally consist of a more extensive implementation of RACM measures; and
- Inclusive of Best Available Control Technology (BACT).

U.S. EPA defines BACT similarly to BACM as an emission limitation based on the, “maximum degree of reduction of each pollutant emitted from or which results from any major emitting facility, which the permitting authority, on a case-by-case basis, taking into account energy, environmental, and economic impacts and other costs, determines is achievable for such facility through application of production processes and available methods, systems, and techniques.”¹³ BACT is also at least as stringent as new source performance standards (NSPS) and national emissions standards for hazardous air pollutants (NESHAPs)¹⁴

MSM is inclusive of the requirements for BACM, but with an additional step, comparing the potential MSMs identified against the measures already adopted in the area to determine if the existing measures are the most stringent.¹⁵ Furthermore, U.S. EPA guidance defined MSM as “the maximum degree of emission reduction that has been required or achieved from a source or source category in any other attainment plans or in practice in any other states and that can feasibly be implemented in the area seeking the extension, such as what LAER represents for new or modified sources under the New Source Review permit program.”¹⁶

Section II. Process for Determining MSM

U.S. EPA prescribes a four-step process for the identification and determination of whether the control measures satisfy the Serious area attainment plan control strategy requirements.

The process for identifying MSM generally follow the same steps as the process for identifying BACM.¹⁷ This is because the Serious area attainment plan control strategy requirements described in § 51.1010 are additive as the plans become more stringent. That is to say, the MSM requirements are inclusive of the requirements for BACM, with additional requirements added to reflect the increased stringency in control levels that result from a bump-up in classification.¹⁸

Figure 2: Process for Determining MSM

This process starts with identifying the sources of PM_{2.5} emissions (both direct and precursor emissions); then expands the analysis in Step 2 to identify all potential control measures that would reduce emissions. Step 3 begins to narrow the scope of analysis by refining the list of all potential control measures to determine which of the control measures are sufficiently stringent to meet the applicable MSM requirements, and to identify which are technically and economically feasible. The final step to adopt any control measures identified through this process, if they are feasible to implement in the South Coast.

Table 2 delves more deeply into this process, showing each required element in the steps listed above for both of the applicable PM_{2.5} Standards.

¹⁷ In accordance with U.S. EPA's prescribed process described in the *TSD for the Maricopa County Serious Area PM₁₀ Plan – 24-Hour Standard* (U.S. EPA 2001), which states, "Given this similarity between the BACM requirement and the MSM requirement, we believe that determining MSM should follow a process similar to determining BACM, but with one additional step, to compare the potentially most stringent measure against the measures already adopted in the area to determine if the existing measures are most stringent." Document is available at: <https://www3.epa.gov/region9/air/phoenixpm/pdf/tsd0901.pdf>

¹⁸ § 51.1003(b)(2)(iii) requires that a submittal requesting a Serious area attainment date extension that is simultaneous with the Serious area attainment plan shall meet the most stringent measure (MSM) requirements set forth at § 51.1010(b), in addition to the BACM and BACT and additional feasible measure requirements set forth at § 51.1010(a)". For more details, see the Serious area attainment plan control strategy requirements identified in 40 CFR § 51.1010(a)(5), § 51.1010(b)(5), and § 51.1010(c)(5)

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

Table 2: MSM Requirements

Standard	12 ug/m3 Annual PM2.5 Standard (2012)
Classification	Serious with Extension
Control Strategy	MSM
<u>Step 1:</u> Identify sources of direct PM _{2.5} and precursor emissions (emissions inventory)	Required “The state shall identify all sources of direct PM_{2.5} emissions and sources of emissions of PM_{2.5} precursors in the nonattainment area in accordance with the emissions inventory requirements...” § 51.1010(b)(1)
<u>Step 2:</u> Identify all potential control measures	Required “The State shall identify all potential control measures to reduce emissions from all sources of direct PM _{2.5} emissions and sources of emissions of PM _{2.5} plan precursors” § 51.1010(b)(2)
<u>Step 2(a):</u> Begin with the area’s current control measures	Recommended ¹⁹ “A state... should be able to start its process using the work already undertaken for the nonattainment area’s RACM and BACM demonstrations and to make updates to the list of potential control measures ”
<u>Step 2(b):</u> Survey other states and nonattainment areas for additional potential control measures	Required “The state shall identify the most stringent measures for reducing direct PM _{2.5} and PM _{2.5} plan precursors adopted into any SIP or used in practice to control emissions in any state ” § 51.1010(b)(2)(i)
<u>Step 2(c):</u> Reconsider and reassess any measures previously rejected	Required “The state shall reconsider and reassess any measures previously rejected by the state during the development of any previous Moderate area or Serious area attainment plan control strategy” § 51.1010(b)(2)(ii)
<u>Step 3:</u> Assess potential control measures’ stringency and feasibility	Required
<u>Step 3(a):</u> Evaluate stringency	Required MSM control levels required
<u>Step 3(b):</u> Assess technological and economic feasibility	Required “The state may make a demonstration that a measure identified... is not technologically or economically feasible to implement in whole or in part by 5 years after the applicable attainment date for the area , and may eliminate such whole or partial measure from further consideration” § 51.1010(b)(3) Assess the technological and economic feasibility of public measure suggestions submitted to CARB as potential control measures
<u>Step 4:</u> If found to be economically and technologically feasible, adopt control measures	Required “The state shall identify, adopt, and implement the most stringent control measures that are included in the attainment plan for any state or are achieved in practice in any state, and can be feasibly implemented in the area” § 51.1010(b)

¹⁹ See U.S. EPA “Fine Particulate Matter National Ambient Air Quality Standards: State Implementation Plan Requirements” July 2016
<https://www.epa.gov/sites/production/files/2016-07/documents/pm25-naaqs-implementation-final-preamble-rule-signature.pdf>

Step 1: Source Category Emissions of Direct PM_{2.5}, NO_x, and Ammonia

The first step required in the MSM evaluation process is to identify and quantify the sources of PM_{2.5}, including direct PM_{2.5} emissions and emissions of precursor pollutants.

Mobile sources, and the fossil fuels that power them, continue to contribute a majority of NO_x emissions, a significant precursor to the formation of particulate matter. On- and off-road heavy-duty mobile sources that burn diesel fuels, including trucks and off-road equipment, also directly emit PM_{2.5}, as do sources primarily regulated at the federal and/or international level, including locomotives, ocean-going vessels, and aircraft. In the South Coast, air quality measurements and modeling have shown that emissions from mobile sources – cars, trucks, and a myriad of off-road equipment – are a significant contributor to ambient PM_{2.5} levels. Overall, mobile sources contribute to approximately 81 percent of NO_x emissions, 17 percent of direct PM_{2.5} emissions, and 25 percent of ammonia emissions in the South Coast. In addition to directly emitted PM_{2.5}, South Coast AQMD modeling demonstrated that gaseous precursors such as NO_x and ammonia are the key precursors to atmospheric formation of PM_{2.5} in the South Coast, while VOC and SOX do not contribute significantly to ambient PM_{2.5} levels exceeding the NAAQS.

The formation of ammonia is a byproduct during the operation of a three-way catalyst (TWC). A TWC operates at near stoichiometric conditions, varying from slightly rich to slightly lean. Ammonia is generally formed during the slightly rich phase. Compressed Natural Gas (CNG) engines exhibit much higher ammonia than do gasoline engines. For diesel engines, ammonia emissions are inherently low as they do not use TWC technology. But newer engines employ Selective Catalytic Reduction (SCR). This technology uses ammonia for NO_x aftertreatment. Unreacted ammonia can be emitted as part of this process (ammonia slip). Estimates of ammonia in emissions inventory models are informed by in-use data collected from dynamometer tests or portable emissions measurement systems (PEMS). Current on-road assumptions are documented in Section 3.3 of the EMFAC2021 technical documentation.²⁰ CARB programs that drive mobile sources to zero-emission vehicles and engines, including regulations such as the Advanced Clean Cars, Advanced Clean Trucks, and the Advanced Clean Fleets Regulations, will provide ammonia emission reduction benefits.

Residential and commercial buildings in California are the source of about 66 tpd NO_x statewide due to natural gas combustion.²¹ Nearly 90 percent of building NO_x emissions are due to space and water heating, with the remaining 10 percent attributable to cooking, clothes drying, and other miscellaneous end uses. Space and water heating comprise nearly 90 percent of all building-related natural gas demand. Buildings also contribute to approximately 25 percent of California's GHG emissions when accounting for fossil fuels consumed onsite and through electricity demand as well as refrigerants

²¹ CARB's Criteria Emission Inventory CEPAM: 2019 Version - Standard Emission Tool

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

used in air conditioning systems and refrigerators. The fuels we use and burn in buildings, primarily natural gas, for space and water heating contribute significantly to building-related criteria pollutant and GHG emissions, and provide an opportunity for substantial emissions reductions where zero-emission technology is available.

Steps 2 and 3: Identification and Evaluation of Potential MSM Control Measures

The second and third steps required in the MSM evaluation process have been grouped together in this chapter so that the control measures for each sector can be more cohesively identified and evaluated.

STEP 2: IDENTIFICATION OF POTENTIAL MSM CONTROL MEASURES

Step 2 calls for the identification of all possible control measures for each of the sources of PM_{2.5} and NO_x identified in Step 1.²² To satisfy the Act's MSM requirements, this is a three-part process.

Step 2(a): California's Control Measures

The identification of all potential control measures begins with an analysis of California's control program. Due in part to the severity of its air quality needs, and in part to unique authority provided under the Act, California's mobile source controls go far beyond other states' and even national programs, and thus provides an excellent starting place in identifying a comprehensive range of mobile source control measures, as required by the Act. This approach also aligns with U.S. EPA guidance, which suggests starting the identification process with any controls previously identified in prior Moderate or Serious SIPs for the nonattainment area.²³

Step 2(b): Other States' and Nonattainment Areas' Control Measures

The second component required to identify all potential MSM control measures is the identification of any additional control measures used in other states or nonattainment areas, and an assessment of their stringency relative to the control measures in the proposed South Coast SIP.^{24, 25} The purpose is to identify whether there are additional potential MSM control measures used to control mobile emissions of direct PM_{2.5} and/or NO_x in other states or nonattainment areas that are more stringent than the measures included in the proposed South Coast SIP. If this assessment finds that there are more stringent measures in use elsewhere – and if they are found to be sufficiently stringent and technically and economically feasible to implement in the South Coast (see Step 3) – the Act requires that any such measures are adopted and implemented

²² In a departure from previous SIP guidance, EPA guidance indicates that there are no *de minimis* source categories for this plan. Thus, emissions of direct PM_{2.5} and PM_{2.5} precursors (i.e. NO_x) from all mobile source categories must be controlled in the South Coast, and meet the applicable MSM requirements. See U.S. EPA April 2016 "SIP Requirements Rule" 81 FR 58010 <https://www.gpo.gov/fdsys/pkg/FR-2016-08-24/pdf/2016-18768.pdf>

²⁵ U.S. EPA "Fine Particulate Matter National Ambient Air Quality Standards: State Implementation Plan Requirements" July 2016

CARB Control Program MSM Analysis for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan

in the South Coast's plan (see Step 4), in order to meet the requirements that the area, "attain the standard as expeditiously as practicable."²⁶

Identification

U.S. EPA guidance provides recommendations for possible resources to assist in the search for other control measures used in other states or nonattainment areas, including:²⁷

- Other states' control programs (including those measures identified in U.S. EPA's list of national, state and/or local air quality agencies' control measures);²⁸
- U.S. EPA's "Menu of Control Measures" for PM_{2.5}; ²⁹ and
- U.S. EPA's mobile-specific control measures for PM_{2.5}.³⁰

Beyond these suggested resources, CARB staff has also taken additional steps to identify any additional control measures currently in use in jurisdictions outside of California. This process included inquiries to U.S. EPA staff in Region 9, as well as inquiries to CARB technical staff that are engaged in developing control strategies across a wide range of sources throughout the agency, including passenger vehicles, heavy-duty trucks and buses, off-road equipment, and fuels. Furthermore, CARB staff has performed internet searches of other jurisdictions' control measures to ensure that our research process for this appendix identifies any control programs that have been more recently developed and which therefore may not otherwise be reflected in the abovementioned resources specified by U.S. EPA.

Assessment

In order to identify the most stringent suite of control measures currently, "adopted into any SIP or used in practice to control emissions in any state,"³¹ CARB staff has identified in the tables included in Section IV Step 2(b) the most stringent suite of control measures in the nation, for each source category. Staff has assessed the relative stringency of measures based on the efficiency of a given measure or control technology to reduce the level of emissions from that source category – for example, by comparing the technical capacity for a given control measure to reduce in-use emissions from the on-road heavy-truck fleet, relative to other potential control measures that target the same emission source(s) for reductions. This assessment demonstrates that, for each source category, the suite of control measures included in

²⁶ § 51.1010(b)(4) and § 51.1004(a)(3)

²⁷ U.S. EPA April 2016 "SIP Requirements Rule" 81 FR 58010 <https://www.gpo.gov/fdsys/pkg/FR-2016-08-24/pdf/2016-18768.pdf>

³⁰ U.S. EPA <https://www.epa.gov/advance/control-measures-programs-pm>. Accessed April 24, 2018

³¹ Per MSM requirements in 40 CFR § 51.1010(b)(2)(i) and § 51.1010(c)(2)(i), which call for the identification of the most stringent suite of control measures in any state or nonattainment area.

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

the proposed South Coast SIP are, in aggregate, the most stringent that are in use in any state or adopted into any SIP and in many cases go beyond MSM requirements.

Step 2(c) Reconsideration and reassessment of any control measures previously rejected as infeasible

The final component required to identify all potential MSM control measures is to reconsider and reassess any control measures proposed in prior Moderate or Serious SIPs for the South Coast that were previously rejected as infeasible.³²

CARB staff reviewed all previous South Coast PM_{2.5} SIPs³³ and found that we did not identify any mobile source control measures as infeasible in previous Moderate or Serious attainment plan control strategies for the South Coast.

During the public process for the 2022 State SIP Strategy, community-based organizations and members of the public suggested additional control measures that CARB could develop. Some of the public member suggestions have been integrated into measures committed to in the 2022 State SIP Strategy, while CARB staff is exploring the feasibility of a few remaining suggestions. The public measure suggestions, and any applicable resultant measures within the 2022 State SIP Strategy, are discussed below, and discussed in more detail in Section IV, Step 3(b): Evaluation of Feasibility, for each relevant source category.

Light-Duty Public Measure Suggestions:

- **Enhanced Transportation Choices**
CARB staff is continuing to explore this suggested measure and how it can meet the Act requirements for SIP measure approvability.
- **Enhanced Bureau of Automotive Repair Consumer Assistance Program**
CARB staff is continuing to explore this suggested measure and how it can meet the Act requirements for SIP measure approvability.
- **Light-Duty Vehicle Fleet Regulation**
CARB staff is continuing to explore this suggested measure. CARB staff anticipate that the recently adopted Advanced Clean Cars II regulation, along with existing CARB regulations and current State incentive programs, achieve a significant amount of the benefits that this suggested measure would accomplish.

Medium- and Heavy-Duty Public Measure Suggestions:

- **On-Road Heavy-Duty Vehicle Useful Life Regulation**
CARB staff has developed the Zero-Emission Trucks measure in response to receiving this public measure suggestion.

³² Identification of any control measures that were previously rejected as infeasible in prior Moderate or Serious SIPs for the area is a requirement for MSM, not BACM. See 40 CFR § 51.1010(b)(2)(ii) and § 51.1010(c)(2)(ii)

³³ See CARB's list of South Coast Air Quality Management Plans at: <https://ww2.arb.ca.gov/our-work/programs/california-state-implementation-plans/nonattainment-area-plans/south-coast-air>

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

- **Additional Incentive Programs: Zero-Emission Trucks**
CARB staff has developed the Zero-Emission Trucks measure in response to receiving this public measure suggestion.

Facility-Based Public Measure Suggestion:

- **Indirect Source Rule**
CARB staff has been investigating the feasibility and potential benefits of this suggested measure, and is continuing to explore this suggested measure and how it can meet the Act requirements for SIP measure approvability. Nonetheless, CARB staff have included an Indirect Source Rule as one potential element of the Zero-Emission Trucks measure.

Commercial and Residential Building Appliances Public Measure Suggestion:

- **Additional Building Emission Standards**
CARB staff has developed the Zero Emission Standard for Space and Water Heaters measure in response to receiving this public measure suggestion.

Other Public Measure Suggestions:

In addition to the above-described public measure suggestions for source categories included in this analysis, CARB also received additional public measure suggestions for categories that are not included in the scope of this analysis. This includes public measure suggestions for stationary sources (the BACT/BARCT Determination public measure suggestion) and for pesticides (the Pesticide Regulation public measure suggestion). The Pesticide Regulation public measure was developed into a measure for the 2022 State SIP Strategy, but which is not described in this analysis because ROG emissions are not a significant precursor emission to PM formation in the South Coast.

STEP 3: EVALUATION OF STRINGENCY AND FEASIBILITY

While the focus of Step 2 is on expanding the scope of analysis to ensure that all possible control measures are identified and incorporated into a list of potential MSM control measures, Step 3 focuses on narrowing that list to identify and discard from further consideration any measures that do not satisfy the applicable requirements for stringency and feasibility. Step 3 therefore calls for an evaluation of each of the potential MSM control measures identified in Step 2, in order to evaluate first whether they satisfy the required level of stringency of each control measure; and secondly, whether they are technically and economically feasible to implement in the South Coast.

Step 3(a): Evaluating Stringency

For a potential control measure to meet the definition of MSM, CARB staff must demonstrate that the measure satisfies stringency requirements in terms of both:

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

- (i) the efficiency of a given measure or control technology to reduce the level of emissions from a specific mobile source, relative to emission controls in place in other states and nonattainment areas; and
- (ii) the timing of when each control measure will begin to be implemented, relative to each plan's timing milestones and deadlines.

The Act defines feasibility in terms of both technological and economic feasibility. For the purposes of this analysis of control measures, the Act defines technological feasibility as, “factors including but not limited to a source's processes and operating procedures, raw materials, physical plant layout, and potential environmental impacts such as increased water pollution, waste disposal, and energy requirements.”³⁴

Economic feasibility considerations include capital costs, operating and maintenance costs, and cost effectiveness of the measure.³⁵ Much of the assessment required to evaluate the efficiency of the level of control provided by a given control measure or technology is included in Step 2(b), wherein CARB staff analyzes the control measures in the South Coast's plan relative to those in other states and nonattainment areas.

The assessment of stringency also includes elements of timing, particularly regarding when a control measure will be implemented. U.S. EPA states that MSM should be implemented, “as expeditiously as practicable”.³⁶ U.S. EPA also clarified the requirement for the analyses of the potential control measures, stating that the analysis should include a determination of the earliest date by which a control measure or technology can be implemented in whole or in part.³⁷ For the PM_{2.5} standard discussed in this plan, Table 3 summarizes the required levels of control measures, and the required timeframe for implementation in order to meet the definition of MSM.

Table 3: Implementation and Timing Requirements for MSM

Standard	12 ug/m3 Annual PM2.5 Standard (2012)
Classification Status	Serious with Extension
Type of Plan Required	MSM
Control Measure Requirements	MSM
Definition of MSM (regarding timing)	<u>MSM</u> : implemented in whole or in part by 5 years after the applicable attainment date for the area ³⁸
Attainment deadline	2030
Timeframe for Implementation	MSM if implemented ≤ 2035

Comparing the Stringency of the South Coast's Plan to the Current Control Program

The final step called for in U.S. EPA's process to demonstrate that the suite of control measures included in the proposed 2024 12 µg/m³ annual PM_{2.5} Plan satisfy the stringency definition for MSM is to compare the measures included in the South Coast's plan against the measures already adopted in the proposed South Coast SIP to

³⁴ 40 CFR § 51.1010(a)(3)(i)

³⁵ 40 CFR § 51.1010(a)(3)(ii)

³⁶ U.S. EPA, 2001 *Final TSD for Maricopa County PM₁₀ Nonattainment Area* (page 31). Available at <https://www3.epa.gov/region9/air/phoenixpm/pdf/tsd0901.pdf>

³⁷ 87 FR 60494

³⁸ 40 CFR § 51.1010(b)(3)

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

determine if the existing control measures alone are more stringent.³⁹ CARB staff has compared the current control program to the control measures included in the South Coast's Plan, and has found that:

- The suite of control measures in the South Coast's proposed 2024 12 µg/m³ annual PM_{2.5} Plan include all of the potential MSM measures identified through the processes described above, including measures in the current control program, and new measure commitments that go beyond MSM requirements.
- The suite of control measures in the South Coast's plan is more stringent than the existing control program alone because the plan encompasses both the existing suite of control programs and the new measures committed to in the 2016 and 2022 State SIP Strategies that have yet to be adopted. The new measures exceed the stringency of the current control program for control requirements applying to all mobile source categories, including the passenger vehicle fleet, the on-road heavy-duty fleet, and off-road equipment and engines, as well as residential and commercial building appliances source categories.

Step 3(b): Determination of Technical and Economic Feasibility

The second half of the required process for evaluating the potential MSM measures is an assessment of their economic and technical feasibility. As part of this process, the Act directs that the state may eliminate any control measures identified in Step 2 from further consideration if it is demonstrated to be technologically or economically infeasible to implement in the South Coast within the specified timeframes.

Per U.S. EPA's guidance and precedence, this requirement is not required to be applied unless a potential MSM control measure is rejected from inclusion in the SIP on the grounds of feasibility.⁴⁰ Nonetheless, CARB staff has conducted an initial assessment of technical feasibility for many of the mobile source control measures in the 2016 State SIP Strategy, and the 2022 State SIP Strategy, as well as through the technology assessments that CARB staff has conducted in collaboration with the South Coast AQMD. These Technology Assessments identified the current technological potential for more stringent emission control measures for on- and off-road heavy-duty applications, together with the fuels necessary to power them, along with ongoing review of advanced vehicle technologies for the light-duty sector.⁴¹

Additionally, an economic impact analysis was conducted for the newly proposed measures that were committed to in the 2022 State SIP Strategy.⁴² Furthermore, all control measures that are regulatory in nature must also undergo a rule-specific, rigorous public review process when proposed by staff and/or approved by the Board, as specified by the Administrative Procedures Act (APA). These requirements include

³⁹ U.S. EPA's 2001 *Final TSD for Maricopa County PM₁₀ Nonattainment Area* see page 32. Available at <https://www3.epa.gov/region9/air/phoenixpm/pdf/tsd0901.pdf>

⁴⁰ See page 400 of U.S. EPA's 2001 *Technical Support Documentation for Maricopa County PM₁₀ Nonattainment Area* <https://www3.epa.gov/region9/air/phoenixpm/pdf/tsd30102.pdf> where EPA staff explain that they are applying to Maricopa County's SIP the decision from a Phoenix Serious SIP not to apply this requirement if no potential control measures are rejected.

⁴¹ Technology and Fuel Assessments <http://www.arb.ca.gov/msprog/tech/tech.htm>

⁴² CARB 2022 "2022 State SIP Strategy Appendix A: Economic Analysis" <https://www2.arb.ca.gov/resources/documents/2022-state-strategy-state-implementation-plan-2022-state-sip-strategy>

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

an Initial Statement of Reasons (ISOR) prepared for each proposed CARB regulation, an Environmental Analysis to satisfy California Environmental Quality Act (CEQA) requirements, and an Economic Analysis, including a Standardized Regulatory Impact Assessment (SRIA) for any proposed regulation has an economic impact exceeding \$50 million.

While these processes occur beyond the requirements addressed in this plan, these requirements ensure there will be further opportunity for public and stakeholder input, as well as ongoing technology review and a more refined assessment of costs and environmental impacts as the measures move through CARB's public process for development into proposed regulations.

Step 4: Adopt and Implement Feasible Control Measures

The final step required by this step-wise process is to adopt and implement the feasible control measures identified in Step 3, in order to satisfy MSM requirements. Board adoption of the proposed South Coast SIP for the 12 µg/m³ annual PM_{2.5} standard – including the control measures described in the 2022 State SIP Strategy – will satisfy the requirements of Step 4.

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

Section III. Step 1: Emissions of Direct PM_{2.5}, NO_x, and Ammonia

Table 4 shows the mobile source emissions of direct PM_{2.5}, and Tables 5 and 6 show the mobile source emissions of NO_x, and ammonia, the key precursors to secondary formation of PM_{2.5} in the South Coast.⁴³

Table 4: Direct PM_{2.5} Emissions (tpd) from Mobile Sources in the South Coast

	2018	2030
On-Road Light-Duty Vehicles	2.4	2.1

⁴³ Data from SCAQMD, 2023. CEPAM version 101B

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

It is important to note that these tables reflect only a subset of the total emissions in the South Coast, and do not reflect emissions from stationary and areawide sources.

Many residential appliances, such as water heaters and furnaces, use natural gas or liquefied petroleum gas (fossil fuel) as a fuel source. These appliances have the potential to emit NO_x during combustion. While emissions from buildings represent a small component of total PM_{2.5} and precursor emissions, water and space heaters comprise a large portion of total building-related emissions.

Section IV. Steps 2 and 3: Identification and Evaluation of Potential Control Measures

The second and third steps required in the MSM evaluation process – the identification of potential MSM control measures, and the evaluation of their stringency and feasibility – have been grouped together so that CARB staff can more cohesively identify and analyze control measures for each sector. The sectors analyzed include mobile sources (which are further broken down into sub-categories of passenger vehicles, on-road heavy-duty trucks and buses, and off-road mobile sources), and residential and commercial building appliances.

SECTION 209 WAIVER AND AUTHORIZATION AUTHORITY

Before delving into the sector-specific analysis, however, it is important to discuss the unique position California holds within the Act. In recognition of California's early efforts and extent of air quality challenges, the State has unique authority to regulate emissions from some mobile source categories more stringently than the federal government under the Act's §209(b) waiver provision and §209(b) authorization provision. This waiver provision also allows California to seek a waiver from U.S. EPA to enact more stringent emission standards for passenger vehicles and heavy-duty trucks. While U.S. EPA has primary authority for interstate trucks, aircraft, ships, locomotives, and some farm and construction equipment, the authorization provision allows California to seek authorization from U.S. EPA to enact more stringent emission standards for certain off-road vehicles and engines.

Due to California's unique waiver and authorization authority under the Act, no other state or nonattainment area has the authority to promulgate mobile source emission standards at levels that are more stringent than the federal standards. Other states can elect to match either the federal standards or the more stringent California standards. As such, no state or nonattainment area has a more stringent suite of mobile source emission control programs than California, implying a de-facto level of control at the level of MSM for CARB's current programs.

Over nearly five decades, CARB has consistently sought waivers and authorizations for its new motor vehicle regulations and has received waivers and authorizations for over 100 regulations. The most recent California standards and regulations that have received waivers and authorizations are:

- [The Advanced Clean Cars \(ACC\) Regulations](#) for light-duty vehicles (including the Zero-Emission Vehicle (ZEV) and the Low-Emission Vehicle III (LEV III) Regulations);
- [On-Board Diagnostics II Requirements](#);
- [The Advanced Clean Trucks Regulation](#);
- [The Zero-Emission Airport Shuttle Bus Regulation](#);
- [The Zero-Emission Power Train Certification](#);
- [Heavy-Duty On-Board Diagnostics \(HD OBD\)](#);
- [The Heavy-Duty Vehicle and Engine Regulation](#);

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

- [Heavy-Duty Vehicle and Engine Emission Warranty and Maintenance Provisions](#);
- [Heavy-Duty Truck Idling Requirements](#);
- [The Heavy-Duty Tractor-Trailer Greenhouse Gas \(GHG\) Standards](#);
- [The In-Use Off-Road Diesel Fleets Regulation](#);
- [The Non-Road Compression Ignition \(CI\) Regulation](#);
- [The Large Spark Ignition \(LSI\) Engine and Fleets Regulation](#);
- [The Portable Diesel Equipment Air Toxics Control Measure \(ATCM\)](#);
- [The Portable Equipment Registration Program \(PERP\)](#);
- [The Small Off-Road Equipment \(SORE\) Regulation](#);
- [The Commercial Harbor Craft \(CHC\) Regulation](#);
- [The Transport Refrigeration Unit \(TRU\) ATCM](#);
- [The Off-Highway Recreational Vehicles Regulation](#);
- [The Mobile Cargo Handling Equipment \(CHE\) Regulation](#); and
- [The Spark Ignition Marine Engine and Boat Regulation](#).

Further, CARB has recently submitted waiver and authorization requests for:

- The Heavy-Duty Omnibus Regulation;
- The Small-Off Road Engine Standard (2021 Amendments);
- The Commercial Harbor Craft (CHC) Regulation (2022 Amendments); and
- The Transport Refrigeration Unit (TRU) Regulation Phase I (2022 Amendments).

CARB's history of progressively strengthening standards as technology advances, coupled with the waiver and authorization process requirements, ensures that California's regulations remain the most stringent in the nation, and that necessary emission reductions from the mobile sector continue. This provision preserves a critical role for California in the control of emissions from new motor vehicles, recognizing that California plays an important leadership role and serves as a "laboratory" state for more stringent motor vehicle emission standards. For example, CARB's LEV I and LEV II, and the ZEV Programs have resulted in the production and sales of over 1.5 million of ZEVs in California since first adopted them in 1990.

Additionally, CARB's 2022 State SIP Strategy⁴⁴ has developed and evaluated potential strategies for mobile source categories under CARB's regulatory authority that will contribute to expeditious attainment of the standards. This effort builds on the measures and commitments already made in CARB's multi-pollutant planning effort that have identified the pathways forward to achieve the State's many air quality, climate, and community risk reduction goals: the 2016 State SIP Strategy, and the 2020 Mobile Source Strategy.

With the 2022 State SIP Strategy, CARB explored and proposed an unprecedented variety of new measures to reduce emissions from the sources under our authority using all mechanisms available. The measures included in the 2022 State SIP Strategy encompass actions to establish requirements for cleaner technologies (both zero-emissions and near zero-emissions), deploy these technologies into the fleet, and

⁴⁴ CARB 2022 State Strategy for the State Implementation Plan (2022 State SIP Strategy) <https://ww2.arb.ca.gov/resources/documents/2022-state-strategy-state-implementation-plan-2022-state-sip-strategy>

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

to accelerate the deployment of cleaner technologies through incentives. As such, the measures included in the 2022 State SIP Strategy have been identified to push beyond the stringency of controls required in the current control program, and have been developed to achieve thus go beyond MSM requirements. ~~definition of emission controls that achieve, “the maximum degree of emission reduction... that can be feasibly implemented in the area.”⁴⁵~~

The California regulations that comprise this rigorous suite of control measures are described in more detail in the following sections.

⁴⁵ U.S. EPA definition of MSM from the 2001 *Final TSD for Maricopa County PM₁₀ Nonattainment Area* (page 31). Available at <https://www3.epa.gov/region9/air/phoenixpm/pdf/tsd0901.pdf>

On-Road Light-Duty Vehicles

On-road light-duty vehicles, often referred to as passenger vehicles, include motorcycles, passenger cars, and light to mid-sized trucks and SUVs. The vast majority of these vehicles currently have gasoline powered internal combustion engines, however this sector is projected to increasingly rely on electric drive vehicles of varying types (e.g. battery electric, plug-in hybrid, or fuel cell electric vehicles).

STEP 2(A): CALIFORNIA'S LIGHT-DUTY CONTROL MEASURES

Since setting the nation's first motor vehicle exhaust emission standards in 1966 that led to the first pollution controls, California has dramatically tightened emission standards for light-duty vehicles. Through CARB regulations, today's new cars pollute 99 percent less than their predecessors did in 1975. In 1970, CARB required auto manufacturers to meet the first standards to control NO_x emissions along with hydrocarbon emissions, which together form smog. The simultaneous control of emissions from motor vehicles and fuels led to the use of cleaner-burning reformulated gasoline (RFG) that has removed the emissions equivalent of 3.5 million vehicles from California's roads.

Light- and medium-duty vehicles are currently regulated under California's ACC program, which includes the LEV III and ZEV programs. The ACC program combines the control of smog, soot-causing pollutants, and greenhouse gas emissions into a single coordinated package of requirements for model years 2015 through 2025. Since CARB first adopted it in 1990, the Low Emission Vehicle Program (LEV and LEV II) and Zero-Emission Vehicle (ZEV) Program have resulted in the production and sales of over 1.5 million (ZEVs) in California. Advanced Clean Cars 2 (ACC2), a measure from the 2016 State SIP Strategy, is a significant effort critical to meeting air quality standards that was adopted in August 2022. ACC2 has the goal of cutting emissions from new combustion vehicles while taking all new vehicle sales to 100 percent zero-emission no later than 2035.

For passenger vehicles, the 2022 State SIP Strategy includes actions to increase the penetration of ZEVs by targeting ride-hailing services offered by transportation network companies through the Clean Miles Standard regulation in order to reduce GHG and criteria pollutant emissions, and promote electrification of the fleet. For motorcycles, the 2022 State SIP Strategy proposes more stringent exhaust and evaporative emissions standards along with zero-emissions sales thresholds. The primary goal of the On-Road Motorcycle New Emissions Standard measure is to reduce emissions from new, on-road motorcycles by adopting more stringent exhaust and evaporative emissions standards along with zero-emissions sales thresholds.

CARB is also active in implementing in-use programs for owners of older dirtier vehicles to retire them early. The "car scrap" programs, like Clean Cars 4 All and Clean Vehicle Rebate Project provide monetary incentives to replace old vehicles with zero-emission vehicles. Other California programs and goals, such as the 2012 Governor's Executive Order to put 1.5 million zero-emission vehicles on the road by 2025 – which was

CARB Control Program MSM Analysis for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan

attained two years early in 2023 – have produced substantial and cost-effective emission reductions from the light-duty vehicle sector.⁴⁶

Taken together, California's emission standards, fuel specifications, and incentive programs for on-road light- and medium-duty vehicles represent all measures that are technologically and economically feasible within California. As a result of these efforts, light-duty vehicle emissions in the South Coast have been reduced significantly since 1990 and will continue to go down through 2030. From today, light-duty vehicle NO_x emissions are projected to decrease by nearly 65 percent by 2030.

Figure 3: Light-Duty Control Measures

NEW VEHICLE STANDARDS

Emission Standards and ZEV Requirements

California is the only state with the authority to adopt and enforce emission standards for new motor vehicle engines that differ from the federal emission standards, which enables CARB to develop more stringent motor vehicle control measures than other states. Adopted in 2012, the **ACC I** program is a suite of regulations that ensure emission reductions from the State's passenger vehicle fleet. In 2013, U.S. EPA issued a waiver for the ACC I Program.⁴⁷

CARB's ACC I program has in recent years been a major driver of turnover to and zero and near-zero emission vehicles in the light-duty sector, providing significant emission reduction benefits. ACC I brought together three major regulations that were previously separate, combining the control of criteria pollutants and greenhouse gas emissions into

⁴⁷ U.S. EPA 2013 "California State Motor Vehicle Pollution Control Standards; Advanced Clean Car Program; Final Notice of Decision" Federal Register January 9, 2013 Volume 78, Number 6 pp. 2211 – 2145. <https://www.gpo.gov/fdsys/pkg/FR-2013-01-09/pdf/2013-00181.pdf>

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

a single coordinated set of requirements for light-duty vehicles of model years 2015 through 2025.

- Two of these regulations, the **LEV III GHG** and **LEV III Criteria Emission** rules, are fleet average performance standards for new vehicles that provide for continued annual emission reductions as the stringency increases through 2025. When fully phased-in, these requirements will achieve near-zero emission levels from new light-duty vehicles. These programs apply to the entire light-duty fleet by setting an average emissions requirement across all new vehicles that creates inherent market flexibility for compliance.
- The third regulation, the **ZEV Regulation**, focuses on advanced technology development and fleet penetration of ZEVs (i.e. battery electric vehicles and hydrogen fuel cell vehicles), and plug-in hybrid electric vehicles (PHEVs) in order to enable manufacturers to successfully meet 2018 and subsequent model year requirements. The ZEV regulation ensures that advanced electric drive technology is commercialized and brought to production scale for cost reductions by 2025, in order to ensure that these low-emission technology vehicles transition from demonstration phase to full commercialization in a reasonable timeframe to meet long-term emission reductions goals. The ZEV amendments for 2018 and subsequent model years in the ACC program are intended to achieve commercialization through simplifying the regulation and pushing technology to higher volume production in order to achieve cost reductions.

The ACC I program has ushered in a new zero emission passenger transportation system. The success of this program is evident: California is the world's largest market for Zero Emission Vehicles (ZEVs), with 119 passenger vehicle models available today, including battery-electric, plug-in hybrid electric, and fuel cell electric vehicles.⁴⁸ A wide variety are now available at lower price points, attracting new consumers. In April 2023, the Governor's 2012 target of 1.5 million ZEVs on the road by 2025 was attained two years early, facilitated in part by \$2 billion in ZEV incentive funding and rebates that have been distributed to Californians through programs like the Clean Vehicle Rebate Project and Clean Cars 4 All.⁴⁹ Approximately 21 percent of all new cars sold in California in 2023 have been ZEVs. Californians, who drive only 10 percent of the nation's cars, account for over 40 percent of all zero-emission car sales in the country. The U.S. makes up about half of the world market. This movement towards commercialization of advanced clean cars has occurred due to CARB's ZEV requirements, part of ACC, which affects passenger cars and light-duty trucks.

In support of California's transition to zero-emission vehicles, in 2020, Governor Newsom signed Executive Order N 79 20,⁵⁰ which established a goal that 100 percent of California sales of new passenger cars and trucks be zero-emission by 2035. With this order and many other recent actions, Governor Newsom has recognized that air pollution remains a challenge for California that requires bold action. Zero-emission

⁵⁰ Executive Order N-79-20 <https://www.gov.ca.gov/wp-content/uploads/2020/09/9.23.20-EO-N-79-20-Climate.pdf>

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

vehicle commercialization in the light-duty sector is well underway. Longer-range battery electric vehicles are coming to market that are cost-competitive with gasoline fueled vehicles and hydrogen fuel cell vehicles are now also seeing significant sales. Autonomous and connected vehicle technologies are being installed on an increasing number of new car models. A growing network of retail hydrogen stations is now available, along with a rapidly growing battery charger network.

Advanced Clean Cars II (ACC II), a measure in the 2016 State SIP Strategy that was adopted by the CARB Board in August 2022, imposes the next level of low-emission and zero-emission vehicle standards for model years 2026-2035 that contribute to meeting federal ambient air quality ozone standards and California's carbon neutrality targets. The ACC II regulations will rapidly scale down emissions of light-duty passenger cars, pickup trucks and SUVs starting with the 2026 model year through 2035. The ACC II regulation also takes the State's already growing zero-emission vehicle market and robust motor vehicle emission control rules and augments them to meet more aggressive tailpipe emissions standards and ramp up to 100 percent zero-emission vehicles by 2035 for all new passenger cars, trucks and SUVs sold in California. ACC II is two-pronged: it will drive the sales of zero emission vehicles (ZEV) and the cleanest-possible plug-in hybrid-electric vehicles (PHEV) to 100-percent in California by the 2035 model year through its **Zero Emission Vehicle (ZEV) Regulation**, while also reducing smog- and PM-forming emissions from new Internal Combustion Engine Vehicles (ICEVs) through the **Low Emission Vehicle (LEV) IV Regulation**.

The LEV IV regulation will further increase the stringency of CARB's criteria pollutant emission standards for light- and medium-duty vehicles for MY 2026 – 2035. LEV IV consists of multiple components:

- Prevents potential emission backsliding of ICEVs that is otherwise possible under the existing regulations by applying the exhaust and evaporative emission fleet average standards exclusively to combustion engines. Although the NMOG+NO_x fleet average for light-duty vehicles remains at 30 mg/mi for MY 2026-2035, the medium-duty vehicle fleet average declines from 178 mg/mi to 150 mg/mi for Class 2b and from 247 mg/mi to 175 mg/mi for Class 3. Additionally, LEV IV eliminates the composite standard option for SFTP emissions to ensure maximum emissions control on all test cycles.
- For light-duty vehicles, lowers the maximum NMOG+NO_x exhaust emission rate from 160 mg/mi in MY 2025 to 70 mg/mi in MY 2029; the US06 PM emission rate from 6 mg/mi to 3 mg/mi; and evaporative running loss emission rates from 0.05 g/mi to 0.01 g/mi. For medium-duty vehicles, lowers the maximum NMOG+NO_x exhaust emission rate from 250 mg/mi in MY 2025 to 170 mg/mi in MY 2028 for Class 2b and from 400 mg/mi to 230 mg/mi for Class 3.
- Reduces cold start emissions by applying the emission standards to a broader range of in-use driving conditions. (Starts after the vehicle engine has been shut-off for more than 12 hours are considered cold starts.)
- Medium-duty vehicles with gross combined weight rating above 14,000 lbs. would also be subject to in-use test standards to capture emissions while towing.

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

CARB will further increase the stringency of sales requirements for ZEVs and PHEVs through the ACC II program's ZEV regulation, which will require manufacturers to deliver for sale increasing percentages of ZEVs and PHEVs as a portion of their overall product deliveries between model years 2026 and 2034 and reach 100-percent ZEVs in 2035 (and after). ACC II also includes innovative charging and ZEV assurance measures, which include ZEV warranty and durability requirements, serviceability, and battery labeling requirements.

Break and Tire Wear

Vehicles emit inhalable particles from two major sources: the exhaust system, which has been extensively characterized and regulated; and non-exhaust sources including brake wear, tire and road wear, clutch wear and road dust resuspension. The non-exhaust sources have not been regulated because they are difficult to measure and control. However, with increasingly stringent standards for exhaust emissions, the non-exhaust fraction has become increasingly important. Model predictions suggest that traffic-related emissions of both PM_{2.5} and PM₁₀ will eventually be dominated by non-exhaust sources.

Additionally, there is concern that exposure to these particles may increase in California because proposed regional land use and transportation plans may lead to denser cities and a higher proximity of people to major roadways. Under the ACC program, the regenerative braking of ZEVs and PHEV results in lower PM emissions from brake wear and thus provides non-exhaust PM_{2.5} emission benefits. As increasing numbers of ZEVs enter the fleet, which are characterized by regenerative braking and lower rolling resistance tires, these technologies offer opportunities to reduce PM_{2.5} emissions from the passenger vehicle fleet.

Clean Miles Standard

The **Clean Miles Standard (CMS)** regulation, which was adopted by CARB in 2021 and will be implemented by the California Public Utilities Commission (CPUC), is a regulation to reduce GHG emissions from ride-hailing services offered by transportation network companies (TNCs), on a per-passenger mile basis, and promote electrification of the fleet by setting an electric vehicle mile target. TNCs provide on-demand rides through a technology-based platform that connects passengers with drivers using personal or rented vehicles.

The CMS includes two annual targets – an eVMT target as well as a GHG target in the metric of g CO₂/PMT. The eVMT target would require TNCs to achieve 90 percent eVMT by 2030. The GHG target would require TNCs to achieve 0 g CO₂/PMT by 2030 through electrification as well as other strategies, including increasing shared rides on their platform, improving operational efficiency (route planning and reduced mileage without passengers), and obtaining optional GHG credits. Optional GHG credits may be requested by the TNCs and approved by the CPUC for ride-hailing trips that are connected to mass transit through a verified booking process, and for investing in bicycle and sidewalk infrastructure projects that support active transportation.

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

On-Board Diagnostic (OBD) Systems

OBD systems serve an important role in helping to ensure that engines and vehicles maintain low emissions throughout their full life. OBD systems are designed to identify when a vehicle's emission control systems or other emission-related computer-controlled components are malfunctioning, causing emissions to be elevated above the vehicle manufacturer's specifications. Many states currently use the OBD system as the basis for passing and failing vehicles in their inspection and maintenance programs, as is exemplified by California's Smog Check Program. For light-duty vehicles, all 2000 and newer MY vehicles are inspected by accessing the OBD system to verify that no emission-related faults are present.

California's first ***On Board Diagnostics Regulation (OBD I)*** required manufacturers to monitor some of the emission control components for passenger vehicles, light- and medium- duty vehicles, starting with the 1988 model year. In 1989, CARB adopted ***OBD II***, which required 1996 and subsequent model year passenger cars, light-duty trucks, and medium-duty vehicles and engines to be equipped with second-generation OBD systems, which standardized the system and addressed the shortcomings of the OBD I requirements (OBD I requirements monitored only a few of the emission-related components on a vehicle). U.S. EPA granted CARB a waiver of preemption for the OBD II regulation in 2016.⁵¹

The Board has modified the OBD II regulation in regular updates since initial adoption to address manufacturers' implementation concerns and, where needed, to strengthen specific monitoring requirements. Most recently, the Board amended the regulation in 2021 to require manufacturers to implement Unified Diagnostic Services (UDS) for OBD communications, which will provide more information related to emissions-related malfunctions that are detected by OBD systems, improve the usefulness of the generic scan tool to repair vehicles, and provide needed information on in-use monitoring performance. UDS implementation would be required for all 2027 and subsequent model year light- and medium-duty vehicles and engines, as well as some heavy-duty vehicles and engines.

Emissions Standards for Motorcycles

While representing a relatively small fraction of the emissions coming from the passenger vehicle fleet, CARB has also taken a comprehensive control approach for emissions from motorcycles. For the most part, motorcycles are on-road two-wheeled, self-powered vehicles with engine displacements of 50 cubic centimeters (cc) or greater. First adopted in 1975, ***California's On-Road Motorcycle Regulation*** obtained its first waiver of preemption from U.S. EPA in 1976. The 1975 regulation set emission standards for all motorcycles with engine displacements of at least 50 cc. The ***1998 Amendments to the California Motorcycle Regulation*** affected only Class 3 motorcycles (280 cc or greater) and set a Tier I and Tier II standard for 2004 and 2008

⁵¹ U.S. EPA 2016 "California State Motor Vehicle Pollution Control Standards; Malfunction and Diagnostic System Requirements for 2004 and Subsequent Model Year Passenger Cars, Light-Duty Trucks, and Medium-Duty Vehicles and Engines; Final Notice of Decision" <https://www.gpo.gov/fdsys/pkg/FR-2016-11-07/pdf/2016-26861.pdf> November 7, 2016 Federal Register Volume 81, Number 215 pp. 78143-78149

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

model years, respectively. While CARB has the same emission standard as the federal standard, the California standard applies to engines starting in 2008 rather than 2010 under the federal requirement. The California Motorcycle Regulation controls both exhaust emission standards and test procedures for on-road motorcycles and motorcycle engines. U.S. EPA granted CARB a waiver of preemption for the 1998 amendments in August 2006.⁵² California's motorcycle exhaust emission test procedures are adopted from U.S. EPA's exhaust test procedures (CFR title 40, part 86, subparts E and F).

Since the 1990s, more stringent exhaust emissions standards have been developed by other jurisdictions outside of the United States around the world, most notably the European Union's EU5 standard which became effective in 2020. These stringent exhaust standards have prompted the development of cleaner motorcycles than what are currently required in California, or anywhere in the nation. Thus, the 2022 State SIP Strategy includes the ***On-Road Motorcycle New Emission Standard*** measure, CARB's latest commitment to reduce emissions from motorcycles. While CARB's existing motorcycle evaporative standards are on par with most other jurisdictions around the world, additional evaporative reductions are technically feasible and other vehicle categories regulated by CARB have adopted much lower evaporative emissions standards. For example, CARB's Off Highway Recreational Vehicle (OHRV) category, which includes vehicles closely related to motorcycles such as off-highway motorcycles, requires lower evaporative emissions limits with more robust test methods. Since 2017, CARB has been working closely with many other jurisdictions in the spirit of trying to achieve harmonization where possible on lower and more robust motorcycle emissions standards. Specifically, CARB has worked closely with U.S. EPA, Environment Climate Change Canada, the European Union, and the United Nations. California also currently has no inspection and maintenance program for motorcycles. CARB has determined that tampering with emissions controls is a significant problem for this category.

The On-Road Motorcycle New Emissions Standard is anticipated to reduce emissions from new, on-road motorcycles (motorcycles) by adopting more stringent exhaust and evaporative emissions standards along with zero-emissions sales thresholds. The exhaust standards would be more stringent than current U.S. EPA standards and largely harmonized with European Union 5 (EU 5) standards. The evaporative standards would be more stringent than current U.S. EPA and EU 5 standards. This measure will also require an increase in new Zero-Emissions Motorcycle (ZEM) sales, starting at 10 percent in 2028 and progressing to 50 percent in 2035. CARB staff is in the process of developing new exhaust emissions standards for hydrocarbons (HC), NO_x, CO and nonmethane HC (NMHC) that achieve a large degree of harmonization with more aggressive current European motorcycle emissions standards. CARB would also develop new evaporative emissions standards that largely harmonize with more aggressive current CARB OHRV emissions standards.

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

REDUCING IN-USE EMISSIONS

Inspection and Maintenance (I/M) Program

Although new vehicles sold in California are the cleanest in the world, the millions of passenger vehicles on California roads, and the increasing miles they travel each day make them our single greatest source of NO_x emissions. While the new vehicles in California may start out with very low emissions, improper maintenance or faulty components can cause vehicle emission levels to sharply increase. Studies estimate that approximately 50 percent of the total emissions from late-model vehicles are excess emissions, meaning that they are the result of emission-related malfunctions.

California's **Smog Check Program** works to ensure that the vehicles remain as clean as possible over their entire life. The Bureau of Automotive Repair (BAR) is the State agency charged with administration and implementation of the Smog Check Program. The Smog Check Program is designed to reduce air pollution from California registered vehicles by requiring periodic inspections for emission-control system problems, and by requiring repairs for any problems found. In 1998, the Enhanced Smog Check program began in which Smog Check stations relied on the BAR-97 Emissions Inspection System (EIS) to test tailpipe emissions with either a Two-Speed Idle (TSI) or Acceleration Simulation Mode (ASM) test depending on where the vehicle was registered. For instance, vehicles registered in urbanized areas received an ASM test, while vehicles in rural areas received a TSI test.

In 2009, the following requirements were added in to improve and enhance the Smog Check Program, making it more inclusive of motor vehicles and effective on smog reductions:

- Low pressure evaporative test;
- More stringent pass/fail cutpoints;
- Visible smoke test; and
- Inspection of light- and medium-duty diesel vehicles.

The next major change in the Smog Check Program was due to AB 2289, adopted in October 2010, a new law restructuring California's Smog Check Program, streamlining and strengthening inspections, increasing penalties for misconduct, and reducing costs to motorists. This new law, supported by CARB and BAR, promised faster and less expensive Smog Check inspections by taking advantage of the second generation of OBD software installed on all vehicles. The new law also directs vehicles without this equipment to high-performing stations, helping to ensure that these cars comply with current emission standards. This program will reduce consumer costs by having stations take advantage of diagnostic software that monitors pollution-reduction components and tailpipe emissions. Beginning mid-2013, testing of passenger vehicles using OBD was required on all vehicles model years 2000 or newer.

In the South Coast, Smog Check requirements are consistent with the most stringent of any other I/M program in the nation. Biennial, change of ownership, and initial

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

registration Smog Check inspections ensure that the in-use passenger vehicle fleet continues to operate as cleanly as possible. Additionally, a portion of vehicles must receive their biennial Smog Check inspections at STAR certified test only or test/repair stations that are required to meet high inspection-based standards.

Based on recent CARB analysis in support of the Smog Check Performance Standard Modeling and Program Certification for the 70 Parts Per Billion 8-hour Ozone Standard (CARB Board meeting, March 23, 2023), the Smog Check Program meets the federal I/M requirements for all applicable nonattainment areas classified as Moderate or above, including the South Coast, San Joaquin Valley, Coachella Valley, Western Mojave Desert, San Diego County, Sacramento Metro, Eastern Kern, and Ventura County nonattainment areas, and the 75 parts per billion 8-hour ozone standard for the San Diego County and Eastern Kern nonattainment areas.

CARB staff's discovery of Volkswagen's (VW's) use of illegal defeat devices—software designed to cheat on emissions tests—in certain 2009 to 2016 model year diesel cars that were sold in California illustrates the success and stringency of California's program to control emissions from the in-use passenger vehicle fleet, and to identify excess in-use emissions. Due to the discovery of VW's emissions cheating scandal and subsequent actions to remediate the environmental damages caused by these vehicles' excess emissions, the VW Environmental Mitigation Trust provides about \$423 million for California to fund projects that accelerate the turnover of mobile sources to cleaner, lower-emitting vehicles and engines.

REDUCING VEHICLE MILES TRAVELLED (VMT)

In addition to the potential measures described above to control emissions from on-road mobile sources, reducing vehicle miles traveled (VMT) is also necessary to directly and immediately reduce mobile source NO_x and ROG emissions. CARB works cooperatively with other State agencies, and the local air districts, metropolitan planning organizations (MPOs), and other local entities to implement the Sustainable Communities and Climate Protection Program and related efforts. This involves developing, adopting, and implementing Sustainable Communities Strategies (SCS), which include VMT reduction targets as required under Senate Bill 375. That said, reducing VMT is difficult; many factors influence an individual's travel choices, and these choices interact with one another in a complex manner that is not always well understood. In the 2020 Mobile Source Strategy, CARB identified several strategies that could be undertaken to assist in achieving additional reductions and support implementation of regional SCSs. Building on the strategies identified in the 2020 MSS, in the 2022 State SIP Strategy, CARB committed to the ***Enhanced Regional Emission Analysis in SIPs*** measure, which will reduce VMT from on-road mobile sources through a Transportation Control Measure (TCM), a strategy to reduce emissions or concentration of air pollutants by reducing the number of vehicle trips or VMT or improving traffic flow. This measure was originally proposed as a public measure suggestion, based on the input from community-based organizations and members of

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

the public. During the development of the 2022 State SIP Strategy, CARB staff developed this public measure suggestion into a SIP measure commitment.

CARB is considering the following measures to further reduce ROG and NO_x emissions from on-road motor vehicles by reducing VMT:

- **Change MVEB Development Process:**
CARB would evaluate the existing MVEB development process, including tools and the latest planning assumptions used in the analysis. Based on the review, CARB could modify the framework for developing MVEBs when considering how to address gaps in emissions reductions needed to demonstrate attainment of different NAAQS. This framework could explore additional emissions reductions from the on-road sector to attain the 70 ppb 8-hour ozone standard and progress towards State air quality goals. This framework would need to ensure that the MVEB is consistent with other applicable requirements such as emission inventory, reasonable further progress, control measures, and attainment demonstration.
- **RACM Analysis:**
CARB would compile a comprehensive list of TCMs implemented or considered by federal, state, regional, and local agencies. This list would provide more choices and new measures subject to RACM analysis for potential inclusion as an enforceable measure in the SIP. This effort may also evaluate the emission reduction potential, feasibility, and cost-effectiveness of each TCM on the list. In addition, CARB could consider providing a quantification methodology to improve and standardize the RACM analysis as part of SIPs across air districts. In pursuing this measure, CARB would work in a collaborative effort with U.S. EPA, California MPOs, and air districts to develop the guidance and implement each potential TCM identified through the RACM.
- **Update Guidance for CMAQ and Motor Vehicle Fees:**
CARB would update the methodology and guidelines for estimating the cost-effectiveness of some of the most widely implemented transportation-related air quality projects using CMAQ and motor vehicle fees. Further, these guidelines would establish methods to quantify emission benefits and cost-effectiveness of new available transportation options and technologies. This update may also include critical inputs associated with emissions estimation to streamline the quantification of cost-effectiveness of various transportation projects. This action will accelerate the penetration of new strategies and maximize the emissions reductions from the transportation sector in the near-term. CARB would work with FHWA, the California Department of Transportation, MPOs, and air districts in pursuing this measure.

FUELS

Cleaner fuel has an immediate impact in reducing emissions from the mobile source, and thus represent an important component in reducing NO_x and ROG emissions from

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

the passenger vehicle fleet. California's stringent air quality programs treat motor vehicles and their fuels holistically (as a system, rather than as separate components). As a result, CARB's fuels programs achieve significant reductions in criteria emissions from gasoline-fueled vehicles used in California.

California's Reformulated Gasoline program (CaRFG) sets stringent standards for California gasoline that produced cost-effective emission reductions from gasoline-powered vehicles resulting in California gasoline being the cleanest in the world. California's cleaner-burning gasoline regulation is one of the cornerstones of the State's efforts to reduce air pollution and cancer risk. Reformulated gasoline is fuel that meets specifications and requirements established by CARB. The results from cleaning up fuel can have an immediate impact as soon as it is sold in the State. Vehicle manufacturers design low-emission vehicles to take full advantage of cleaner-burning gasoline properties.

The CaRFG program has been implemented in three phases:

- Phase 1, which was implemented in 1991, eliminated lead from gasoline and set regulations for deposit control additives and Reid vapor pressure (RVP).
- Phase 2 CaRFG (CaRFG2 in 1994) set specifications for sulfur, aromatics, oxygen, benzene, T50, T90, Olefins, and RVP and established a Predictive Model.
- The final and current phase, Phase 3 CaRFG, eliminated, in 1996, the use of methyl-tertiary-butyl-ether in California gasoline.

The use of cleaner-burning gasoline in the South Coast has been required since March 1996. **Phase 3 CaRFG** also revised specifications for Phase 3 gasoline that reduces ozone precursor emissions (including aromatic hydrocarbons and olefins) by ~15 percent and toxic air contaminant emissions by about 40 percent, compared with CaRFG2. The regulation strengthened specification requirements for cleaner-burning gasoline, including:

- Reduced sulfur content. Sulfur inhibits the effectiveness of catalytic converters. Cleaner-burning gasoline enables catalytic converters to work more effectively and further reduce tailpipe emissions.
- Reduced benzene content. Benzene is known to cause cancer in humans. Cleaner-burning gasoline has about one-half the benzene of earlier gasoline, thus reducing cancer risks.
- Reduced levels of aromatic hydrocarbons (ozone precursor).
- Reduced levels of olefins (ozone precursor).
- Reduced Reid vapor pressure, which ensures that gasoline evaporates less readily.
- Two specifications for reduced distillation temperatures, which ensure the gasoline burns more completely, and
- Use of an oxygen-containing additive, such as ethanol, which also helps the gasoline burn more cleanly.

STEP 2(B): OTHER STATES' AND NONATTAINMENT AREAS' LIGHT-DUTY CONTROL MEASURES

Table 7 summarizes the most stringent control measures currently in use in any state or nonattainment that have been identified and discussed for on-road light-duty vehicles. Each of the measures identified in this table are discussed in more detail in this section, below.

Table 7: Comparison of Stringency – Light-Duty Measures

CARB Control Programs Compared to Federal Standards and Control Programs in Other States and Nonattainment Areas

Type of Control Measure	Most Stringent Control Program Identified	Summary of Findings from Analysis	Other Jurisdiction(s) Analyzed
On-Road Light-Duty Vehicles			
New Vehicle Standards			
New Vehicle Standards: Emissions standards (passenger cars)	<p>LEV III program (CARB) MY 2015 - 2025 (part of Advanced Clean Cars I program)</p> <p>LEV IV program (CARB) MY 2026 - 2035 (part of Advanced Clean Cars II program)</p>	<p>17 states have adopted California's Low Emission Vehicle III (LEV III) program, which set fleet average criteria pollutant performance standards for new light- and medium-duty vehicles for MY 2015 - 2025</p> <p>CARB will further increase the stringency of CARB's criteria pollutant emission standards with LEV IV program, a part of ACC II, for MY 2026 – 2035. LEV IV consists of these components:</p> <ul style="list-style-type: none"> Prevents potential emission backsliding of ICEVs that is otherwise possible under the existing regulations by applying the exhaust and evaporative emission fleet average standards exclusively to combustion engines. Although the NMOG+NOx fleet average for light-duty vehicles remains at 30 mg/mi for MY 2026-2035, the medium-duty vehicle fleet average declines from 178 mg/mi to 150 mg/mi for Class 2b and from 247 mg/mi to 175 mg/mi for Class 3. Additionally, LEV IV eliminates the composite standard option for SFTP emissions to ensure maximum emissions control on all test cycles. For light-duty vehicles, lowers the maximum NMOG+NOx exhaust emission rate from 160 mg/mi in MY 2025 to 70 mg/mi in MY 2029; the US06 PM emission rate from 6 mg/mi to 3 mg/mi; and evaporative running loss emission rates from 0.05 g/mi to 0.01 g/mi. For medium-duty vehicles, lower the maximum NMOG+NOx exhaust emission rate from 250 mg/mi in MY 2025 to 170 mg/mi in MY 2028 for Class 2b and from 400 mg/mi to 230 mg/mi for Class 3. Reduces cold start emissions by applying the emission standards to a broader range of in-use driving conditions. (Starts after the vehicle engine has been shut-off for more than 12 hours are considered cold starts.) Medium-duty vehicles with gross combined weight rating above 14,000 lbs. would also be subject to in-use test standards to capture emissions while towing. 	<p>17 States have adopted the LEV III requirements of ACC I under the provisions of Section 177:</p> <ul style="list-style-type: none"> NY, MA, VT, ME, PA, CT, RI, WA, OR, NJ, MD, DE, CO, MN, NV, VA, and NM <p>LEV IV regulations will control emissions of criteria pollutants from the exhaust and fuel systems of conventional motor vehicles. They would apply to vehicles produced and delivered for sale in California beginning with the 2026 model year. They are more stringent than the existing federal Tier 3 standards for the same pollutants from motor vehicles for the 2025 and subsequent model years that were set by the U.S. EPA.</p> <p>Five other states have adopted the new LEV IV from ACC2 under Section 177: MA, OR, WA, VT, and NY</p>
New Vehicle Standards:	ZEV program (CARB) MY 2015 - 2025 (part of Advanced Clean Cars I program)	15 states have matched California's current ZEV Regulation for battery electric vehicles (BEVs), hydrogen fuel cell vehicles (FCEVs), and plug-in hybrid electric vehicles (PHEVs).	15 states have adopted the ZEV requirements of ACC I under the provisions of Section 177:

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

Type of Control Measure	Most Stringent Control Program Identified	Summary of Findings from Analysis	Other Jurisdiction(s) Analyzed
On-Road Light-Duty Vehicles			
Zero-emission Requirements (passenger cars)	ACC II's ZEV Program (CARB) MY 2026 – 2035 (part of Advanced Clean Cars II program)	CARB will further increase the stringency of sales requirements for ZEVs and PHEVs through the ACC II program's ZEV regulation, which will require manufacturers to deliver for sale increasing percentages of ZEVs and PHEVs as a portion of their overall product deliveries between model years 2026 and 2034 and reach 100-percent ZEVs in 2035 (and after). ACC II also includes innovative charging and ZEV assurance measures, which include ZEV warranty and durability requirements, serviceability, and battery labeling requirements	<ul style="list-style-type: none"> NY, MA, VT, ME, CT, RI, WA, OR, NJ, MD, CO, MN, NV, VA, and NM <p>Five other states have adopted the new ZEV standards from ACC2 under Section 177: MA, OR, WA, VT, and NY</p> <p>There are no comparable federal standards for sales of zero-emission vehicles.</p>
New Vehicle Standards: On-Board Diagnostic (OBD) systems requirements	California OBD II Requirements (CARB)	CARB's On-Board Diagnostic II (OBD II) Systems Requirements exceed Federal requirements in stringency. OBD II ensures that the in-use fleet continues to operate as cleanly as possible.	In practice, virtually all vehicles sold in the U.S. are designed and certified to meet California's OBD II requirements, regardless of where in the U.S. they are sold.
New Vehicle Standards: Emissions standards (Motorcycles)	California's On-Road Motorcycle Regulation (CARB) Future Measure: <i>On-Road Motorcycle New Emissions Standards (CARB)</i>	<p>CARB's emission standards and in-use testing for on-road motorcycles (California's On-Road Motorcycle Regulation) set a Tier I and Tier II standard for 2004 and 2008 model years, respectively, for Class 3 motorcycles (280 cc or greater). California's evaporative emission limits for motorcycles exceed the stringency of any other in the nation, while exhaust emission a limits and test procedures are consistent with U.S. EPA's.</p> <p>The 2022 State SIP Strategy committed to the On-Road Motorcycle New Emission Standard, which will further reduce emissions from new-on-road motorcycles through the adoption of more stringent exhaust and evaporative emissions standards along with zero-emissions sales thresholds. The exhaust standards would be more stringent than current U.S. EPA standards and largely harmonized with European Union 5 (EU 5) standards. The evaporative standards would be more stringent than current U.S. EPA and EU 5 standards. This measure will also require an increase in new Zero-Emissions Motorcycle (ZEM) sales, starting at 10 percent in 2028 and progressing to 50 percent in 2035.</p> <p><i>(Note: CARB has committed to pursue the On-Road Motorcycle New Emissions Standard measure, but this measure has yet to be proposed to the Board for approval/adoption)</i></p>	California is the only state with emission control requirements for on-road motorcycles that exceed the stringency of U.S. EPA requirements.
In-Use Emission Controls			
In-Use Emission Controls: Inspection and maintenance program (I/M program)	Smog Check Program (CARB and administered by the California Department of Consumer Affairs' Bureau of Automotive Repair)	The Inspection / Maintenance (I/M) Program testing and in-use emission controls in the South Coast are consistent with the most stringent of any other I/M program in the nation. Biennial, change of ownership, and initial registration Smog Check inspections ensure that the in-use passenger vehicle fleet continues to operate as cleanly as possible. Additionally, a portion of vehicles must receive their biennial Smog Check inspections at STAR certified test only or test/repair stations that are required to meet high inspection-based standards.	32 states and areas have an I/M program in at least a portion of their state or area (AZ, CO, CA, CT, DE, GA, ID, IL, IN, LA, ME, MD, MA, MO, NV, NH, NJ, NM, NC, NY, OH, OR, PA, RI, UT, TN, TX, VA, VT, WA, WI, and DC).

**CARB Control Program MSM Analysis
for the SCAQMD 2024 12 µg/m³ annual PM_{2.5} Plan**

Type of Control Measure	Most Stringent Control Program Identified	Summary of Findings from Analysis	Other Jurisdiction(s) Analyzed
On-Road Light-Duty Vehicles			
		Based on recent CARB analysis in support of the Smog Check Performance Standard Modeling and Program Certification for the 70 Parts Per Billion 8-hour Ozone Standard (CARB Board meeting, March 23, 2023), the Smog Check Program meets the federal I/M requirements for all applicable nonattainment areas classified as moderate or above, including the South Coast Air Basin, San Joaquin Valley, Coachella Valley, Western Mojave Desert, San Diego County, Sacramento Metro, Eastern Kern, and Ventura County nonattainment areas, and the 75 parts per billion 8-hour ozone standard for the San Diego County and Eastern Kern nonattainment areas.	
In-Use Emission Controls: Fleet Rules	Clean Miles Standard (CARB)	<p>The Clean Miles Standard (CMS) regulation, which was adopted by CARB in 2021, is to reduce GHG emissions from ride-hailing services offered by transportation network companies (TNCs), on a per-passenger mile basis, and promote electrification of the fleet by setting an electric vehicle mile target. TNCs provide on-demand rides through a technology-based platform that connects passengers with drivers using personal or rented vehicles.</p> <p>The CMS includes two annual targets – an eVMT target as well as a GHG target in the metric of g CO₂/PMT. The eVMT target would require TNCs to achieve 90 percent eVMT by 2030. The GHG target would require TNCs to achieve 0 g CO₂/PMT by 2030 through electrification as well as other strategies, including increasing shared rides on their platform, improving operational efficiency (route planning and reduced mileage without passengers), and obtaining optional GHG credits. Optional GHG credits may be requested by the TNCs and approved by the CPUC for ride-hailing trips that are connected to mass transit through a verified booking process, and for investing in bicycle and sidewalk infrastructure projects that support active transportation.</p>	CARB staff is unaware of any other state or jurisdiction with VMT reduction programs via Transportation Network Companies (TNCs).
